

Mapping the Zone: Improving Flood Map Accuracy

David Maidment, Chair

Briefing for ASPRS Coastal
Lidar Workshop

November 15, 2009

Presentation Outline

- Overview of Committee Charge
- Review of Elevation for Floodplain mapping study
- Mapping the Zone Report Chapters
 - 1-3 Overview of flood mapping and terrain data
 - 4-5 Inland and Coastal flood mapping
- Overarching Findings

Presentation Outline

- *Overview of Committee Charge*
- Review of Elevation for Floodplain mapping study
- Mapping the Zone Report Chapters
 - 1-3 Overview of flood mapping and terrain data
 - 4-5 Inland and Coastal flood mapping
- Overarching Findings

Committee Charge: Tasks 1 & 2

1. Examine the **current methods** of constructing FEMA flood maps and the relationship between the methods used to conduct a flood map study (detailed study, limited detailed study, automated approximate analysis, or redelineation of existing hazard information), the **accuracy of** the predicted **flood elevations**, and the accuracy of predicted **flood inundation boundaries**.
2. Examine the **economic impacts** of inaccuracies in the flood elevations and floodplain delineations in relation to the **risk class** of the area being mapped (based on the value of development and number of inhabitants in the risk zone).

Committee Charge: Task 3

3. Investigate the impact that various **study components** (i.e., variables) have on the mapping of flood inundation boundaries:

a. **Riverine** flooding

- The accuracy of **digital terrain** information
- **Hydrologic** uncertainties in determining the flood discharge
- **Hydraulic** uncertainties in converting the discharge into a flood water surface elevation

b. **Coastal** flooding

- The accuracy of the **digital terrain** information
- Uncertainties in the **analysis** of the coastal flood elevations

c. **Interconnected ponds** (e.g., Florida)

- The accuracy of the **digital terrain** information
- Uncertainties in the **analysis** of flood elevations

Committee Charge: Tasks 4-6

4. Provide recommendations for **cost-effective improvements** to FEMA's flood study and mapping methods.
5. Provide recommendations as to how the **accuracy** of FEMA flood maps can be better **quantified and communicated**.
6. Provide recommendations on how to better **manage the geospatial data** produced by FEMA flood map studies and integrate these data with other national hydrologic information systems.

Committee Membership

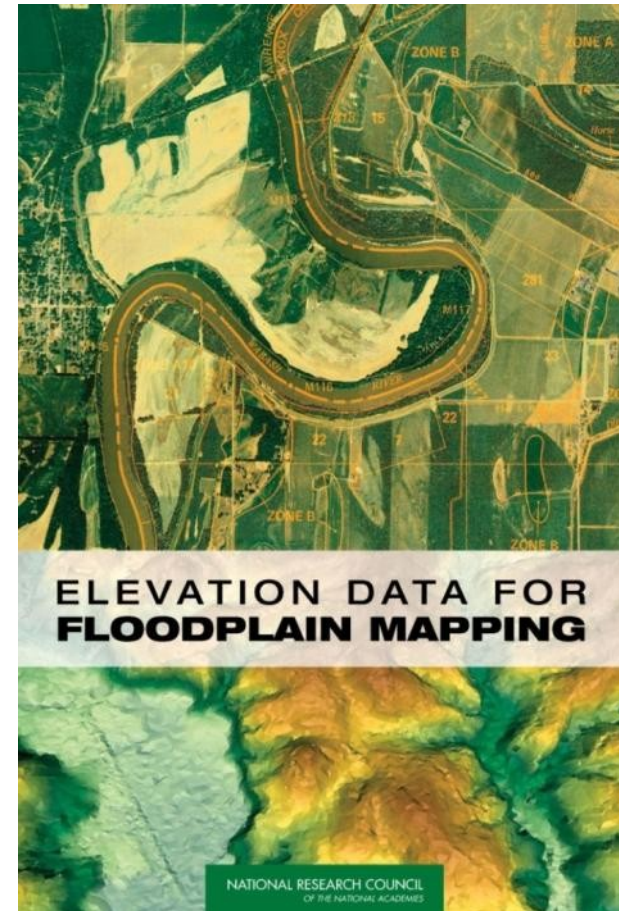

David Maidment, Chair, University of Texas	Practitioners Academics Geodesy Hydrology Coastal Economics Risk
David Brookshire, University of New Mexico	
J. William Brown, City of Greenville, South Carolina	
John Dorman, State of North Carolina	
Gerald Galloway, University of Maryland

David Maune, Dewberry	
Burrell Montz, Binghamton University	
Spencer Rogers, North Carolina Sea Grant	
Karen Schuckman, Pennsylvania State University	
Y. Peter Sheng, University of Florida	
Juan Valdes, University of Arizona	

Presentation Outline

- Overview of Committee Charge
- *Review of Elevation for Floodplain mapping study*
- Mapping the Zone Report Chapters
 - 1-3 Overview of flood mapping and terrain data
 - 4-5 Inland and Coastal flood mapping
- Overarching Findings

Previous NRC Studies: Flood Map Technologies (2007)

- An examination of the accuracy of flood **base map input data**
 - 2D imagery and planimetrics
 - 3D elevation
- Prompted by issues raised by Senate Appropriations Committee staff

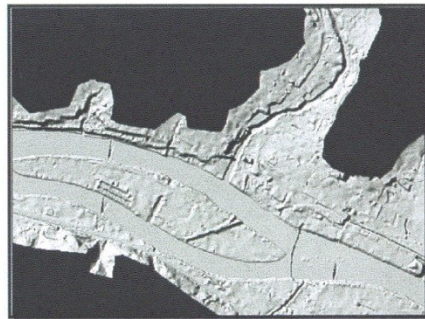

DFIRM Components

'Base map information'

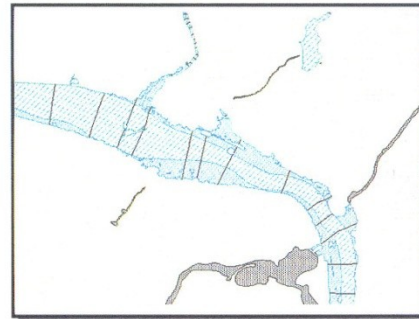

Imagery

Elevation

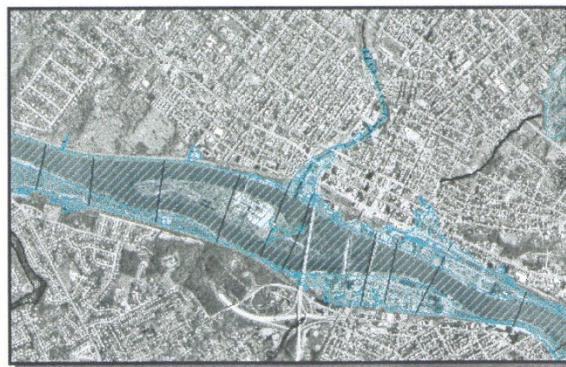

+

Flood Data*

+

=

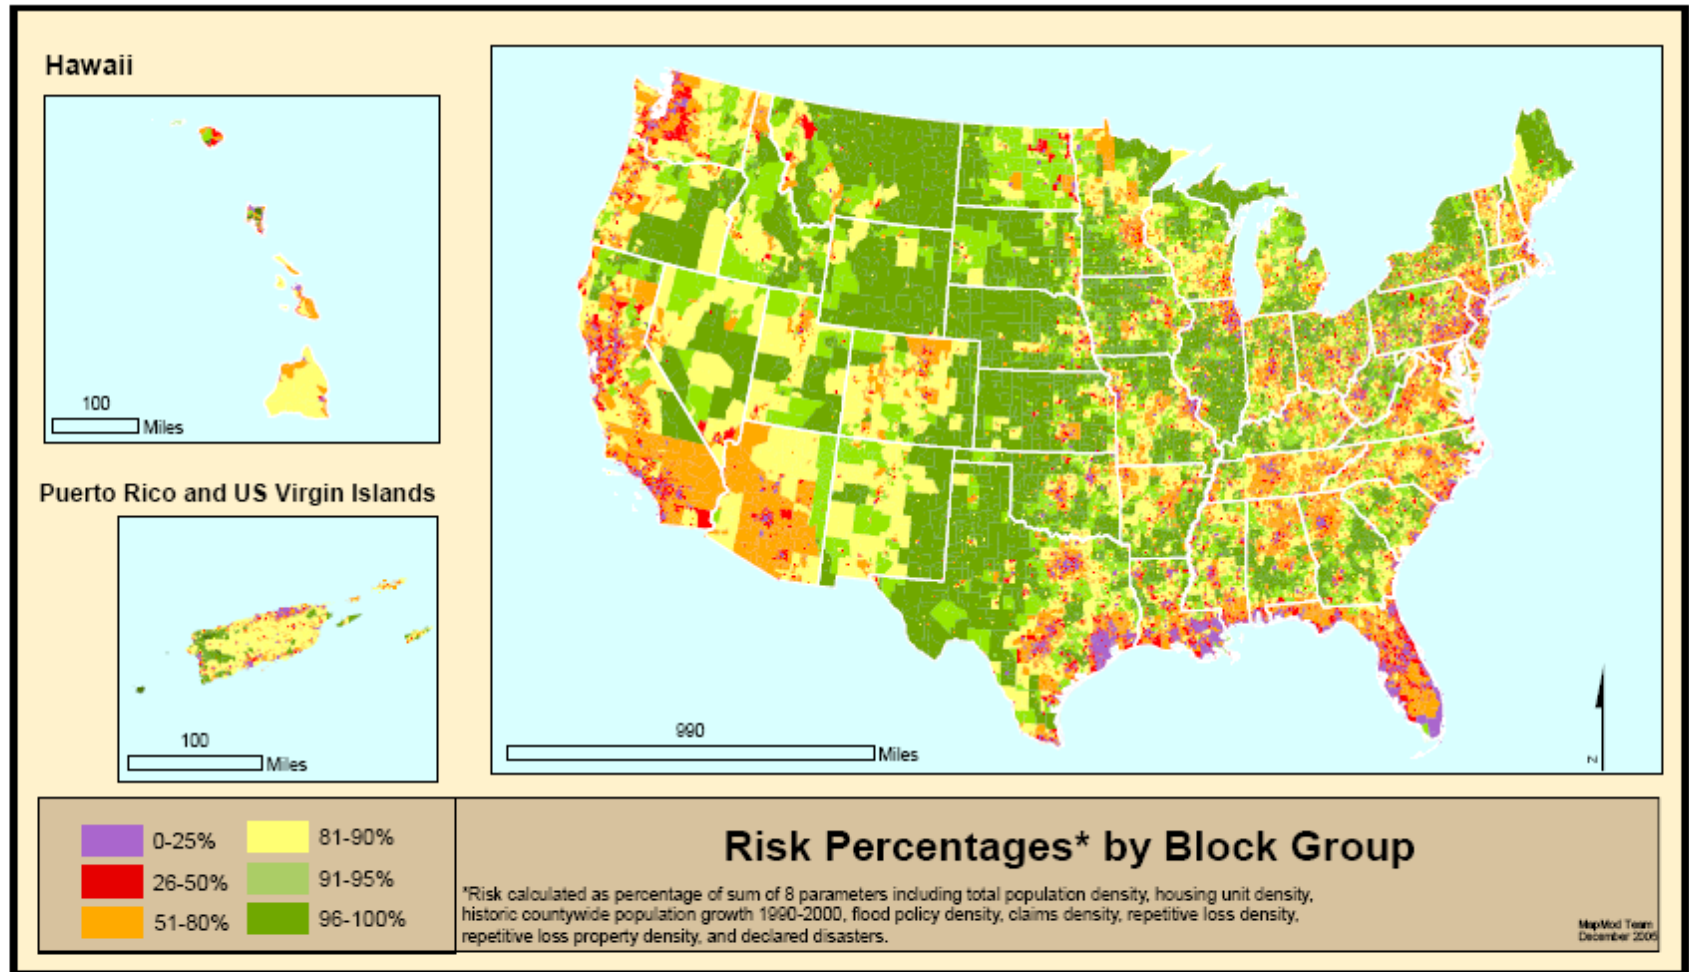

DFIRM

This study addressed the technologies producing Imagery and Elevation data components of the DFIRM

**New, 2-year NRC study sponsored by FEMA will look at Flood Map Accuracy and include analysis of Flood Data component of the DFIRM*

Where is Risk the Greatest?

Scott Edelman (Watershed Concepts)

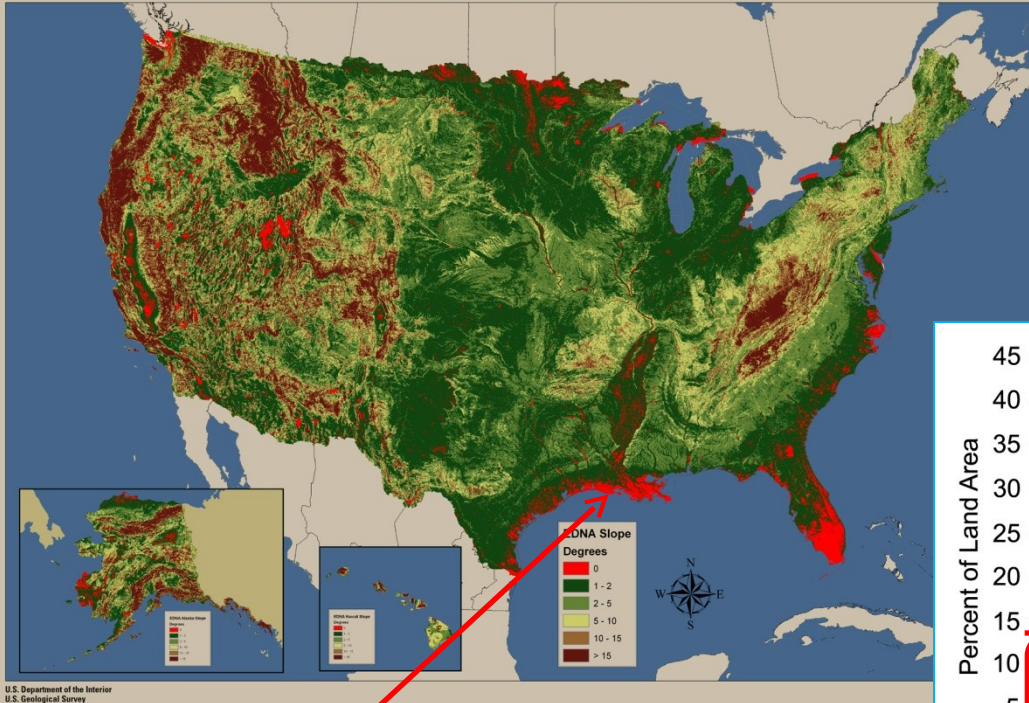

THE NATIONAL ACADEMIES

Advisers to the Nation on Science, Engineering, and Medicine

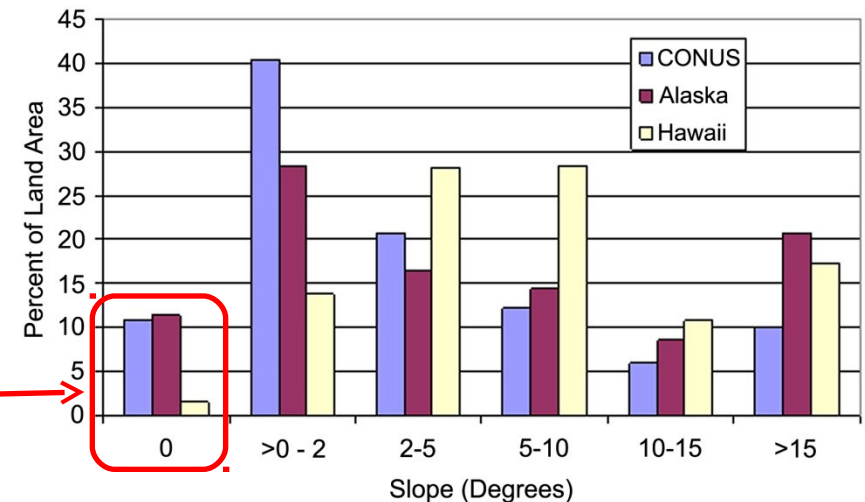

Slope map of the U.S. gives approximate scope of a national elevation program

Elevation Derivatives for National Applications (EDNA) Slope

National Elevation Dataset

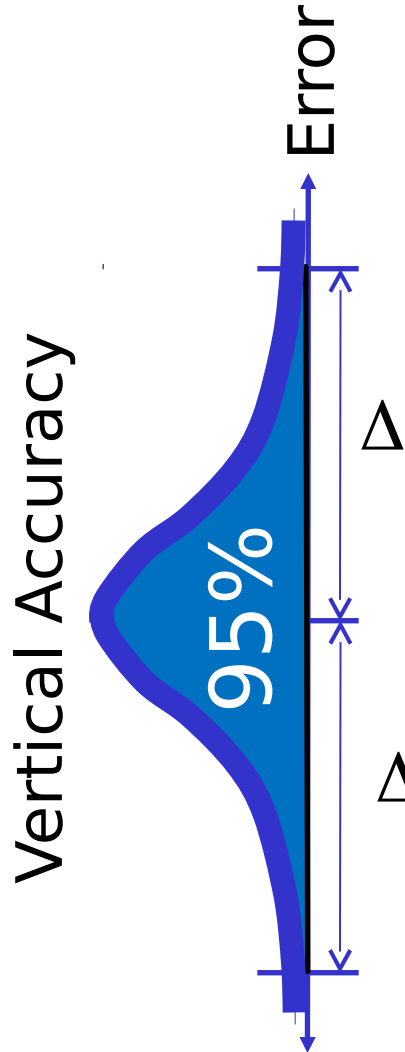

11% of the continental US and Alaska has zero slope in the current National Elevation Dataset, much of which is in high-risk, coastal flooding areas.

THE NATIONAL ACADEMIES

Advisers to the Nation on Science, Engineering, and Medicine

Why LIDAR?

FEMA Flood Map Accuracy Standards

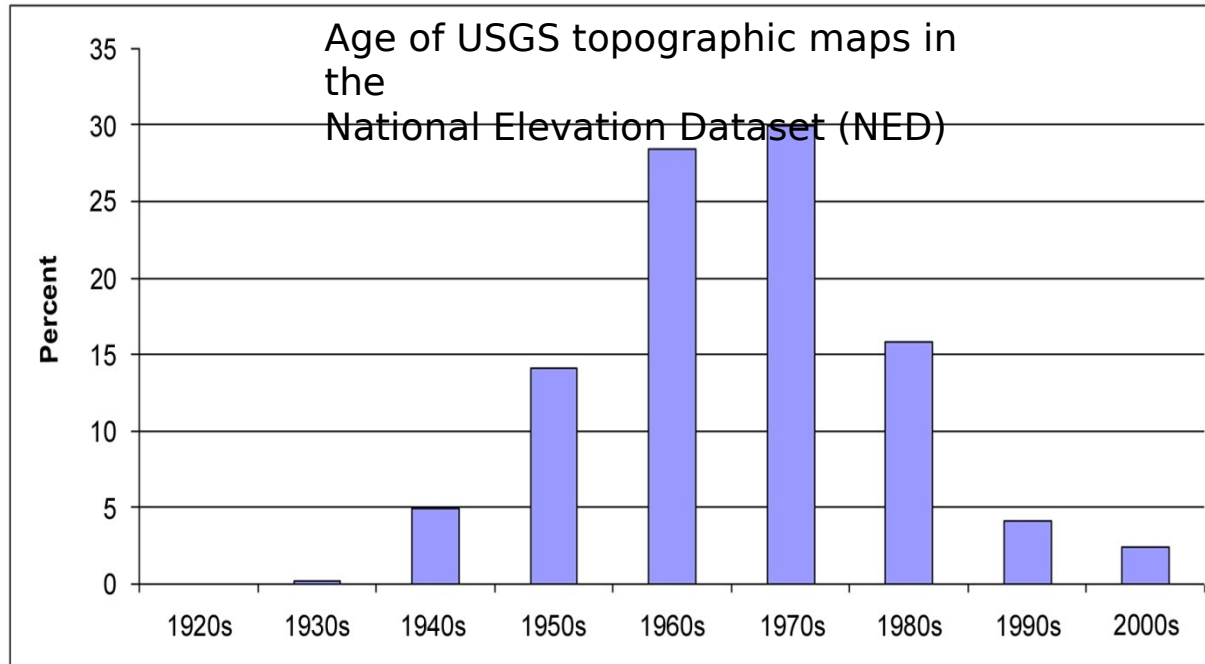

Flat Terrain: $\Delta = 1.2$ ft

Rolling to Hilly Terrain: $\Delta = 2.4$ ft

Δ National Elevation Dataset:

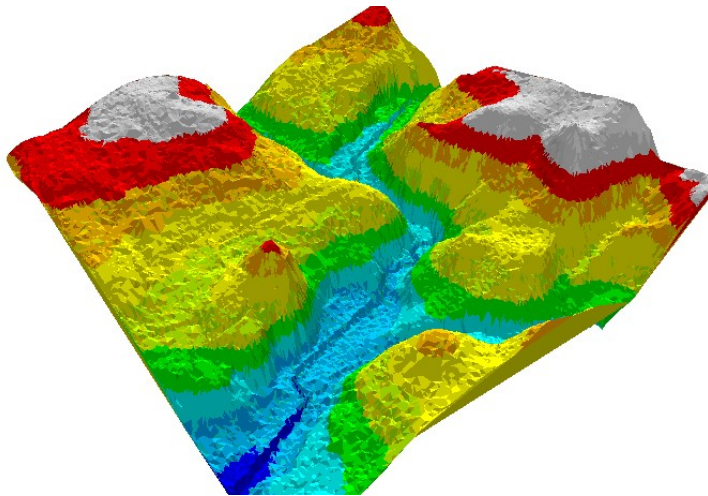

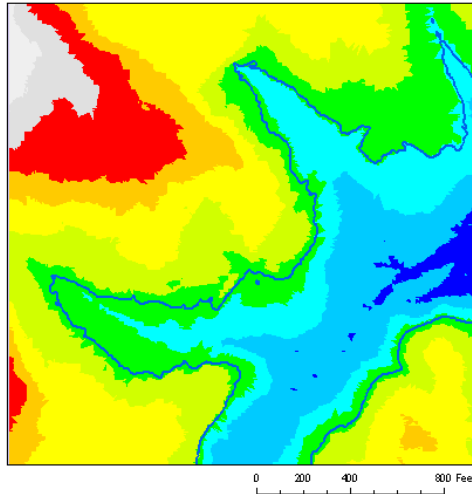

Compared to survey benchmarks: $\Delta = 15$ ft

Elevation for the Nation

- Terrain data in USGS topographic maps are on **average 35 years old** and flood mapping requires data that are either collected or considered for updating within the **last 7 years**.

Base Elevation Data in Detail— Light Detection and Ranging (lidar)

Current 2-D Determinations: Lidar data enables the most accurate delineation of floodplains consistent with current methodology for flood risk determinations based on **horizontal location of a structure** relative to Special Flood Hazard Areas depicted on flat Flood Insurance Rate Maps.

Future 3-D Determinations: Lidar data would also enable accurate flood risk determinations based on the **vertical comparison of a structure's lowest adjacent grade (LAG)** relative to the Base Flood Elevation (BFE)

Conclusions and Recommendations

Rational flood management for the nation requires a **three-dimensional view**, quantifying both the variable Base Flood Elevations (BFEs) throughout the floodplain (vertical) and the areal extent (horizontal) of the 1% annual chance (100-year) flood where the BFEs intersect the terrain surface as depicted by digital elevation models.

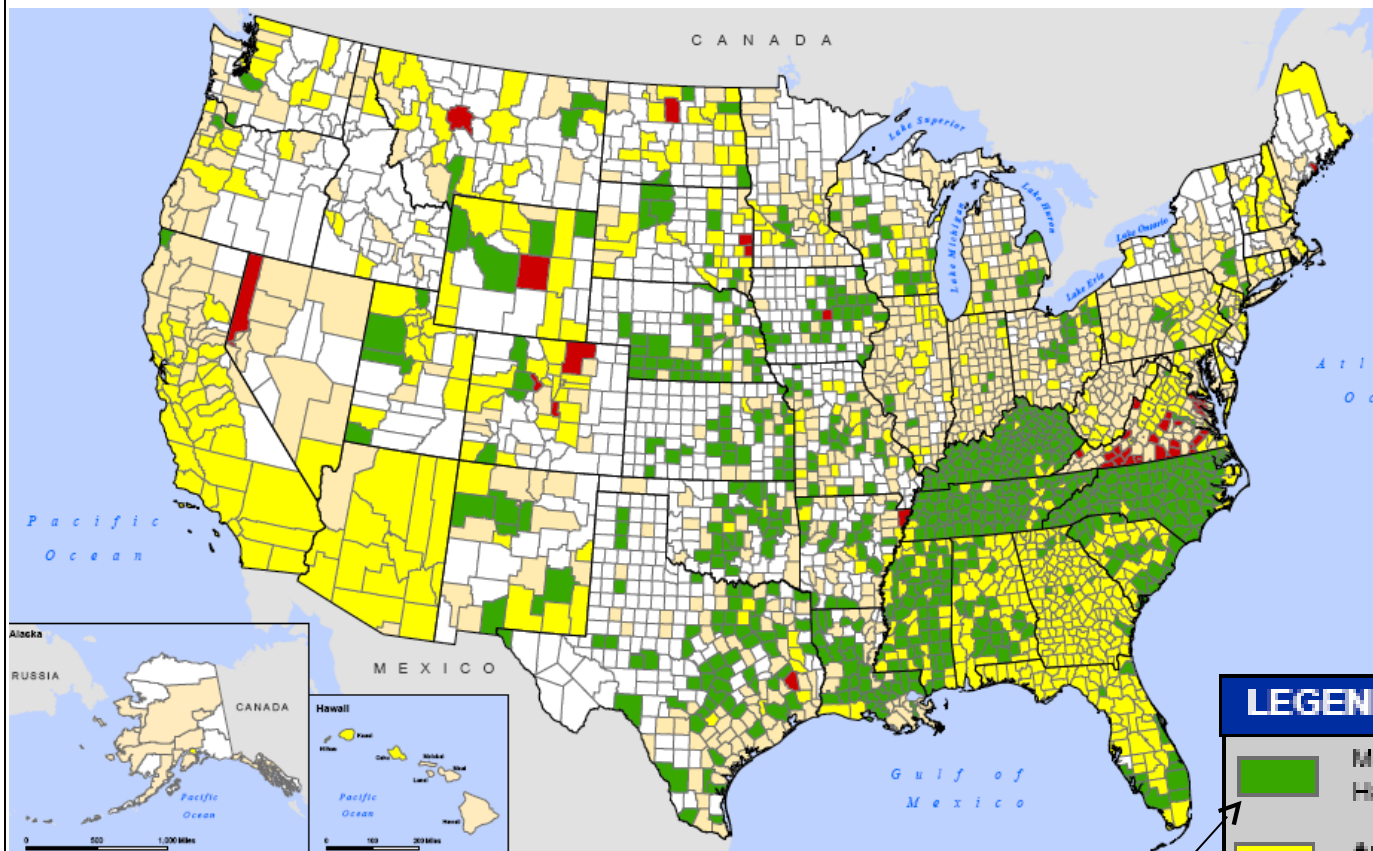

To support the NFIP, analyzing these features in three-dimensions requires **high-accuracy base map elevation data**.

Existing elevation data are about 1/10 as accurate and about 5 times older than needed for the flood mapping task.

SUMMARY: A new digital mapping program for this land surface elevation is needed, which the committee has termed *Elevation for the Nation*

Presentation Outline

- Overview of Committee Charge
- Review of Elevation for Floodplain mapping study
- *Mapping the Zone Report Chapters*
 - *1-3 Overview of flood mapping and terrain data*
 - 4-5 Inland and Coastal flood mapping
- Overarching Findings

Adjusted goal: 92% of population and 65% of land area will have a modernized map

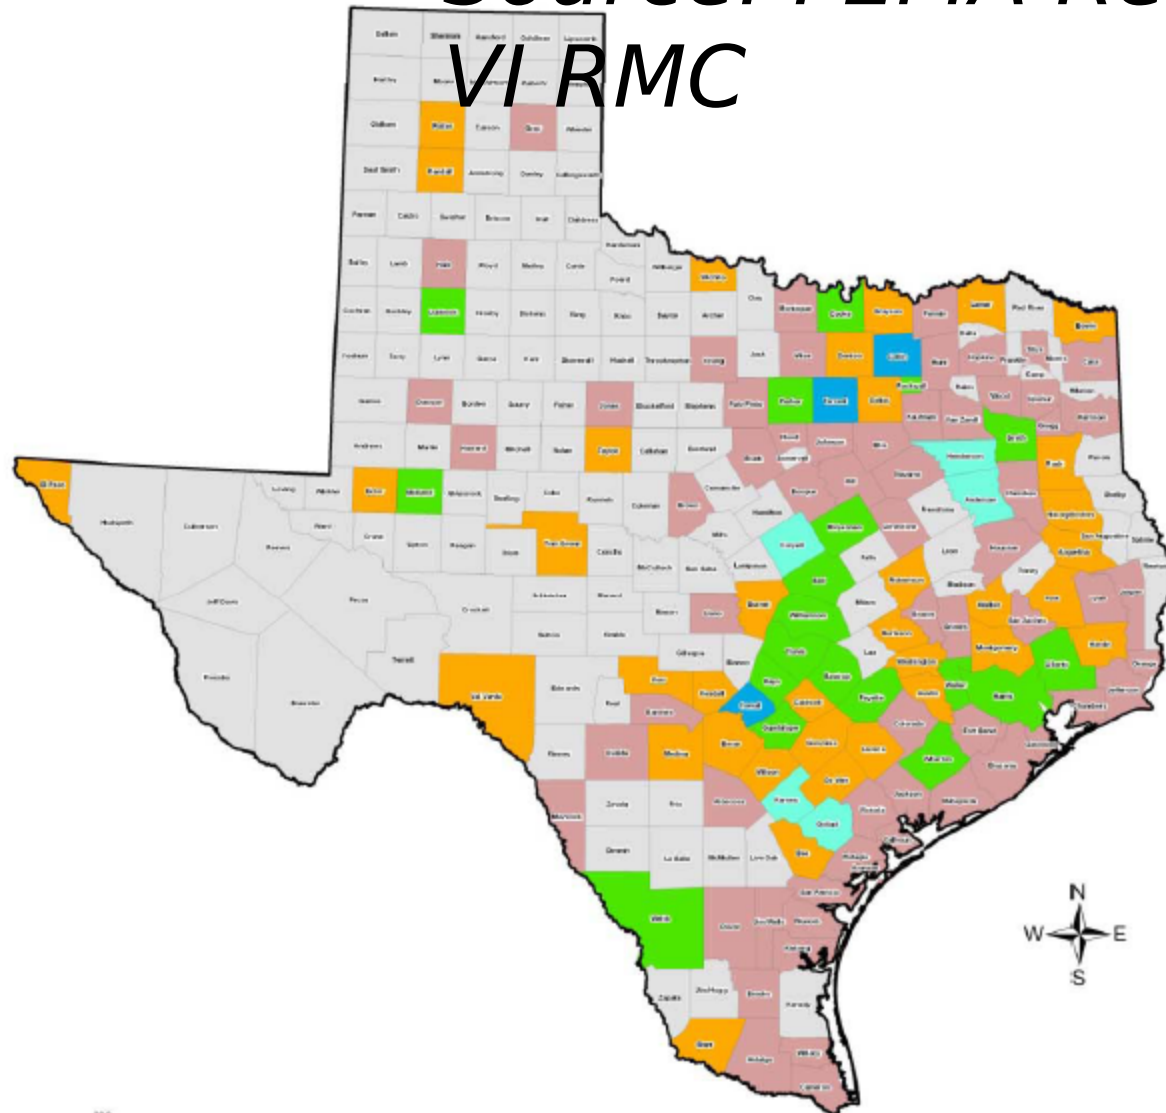

LEGEND

-  Meets or Exceeds National Flood Hazard Data Quality Thresholds
-  Approaches National Flood Hazard Data Quality Thresholds
-  Digital Product Issued
-  Modernized Map Not Yet Issued
-  Study Not Planned

21% of population has maps meeting the floodplain boundary standard and engineering study

Map Modernization in

~~Texas~~ Source: FEMA Region
VI RMC

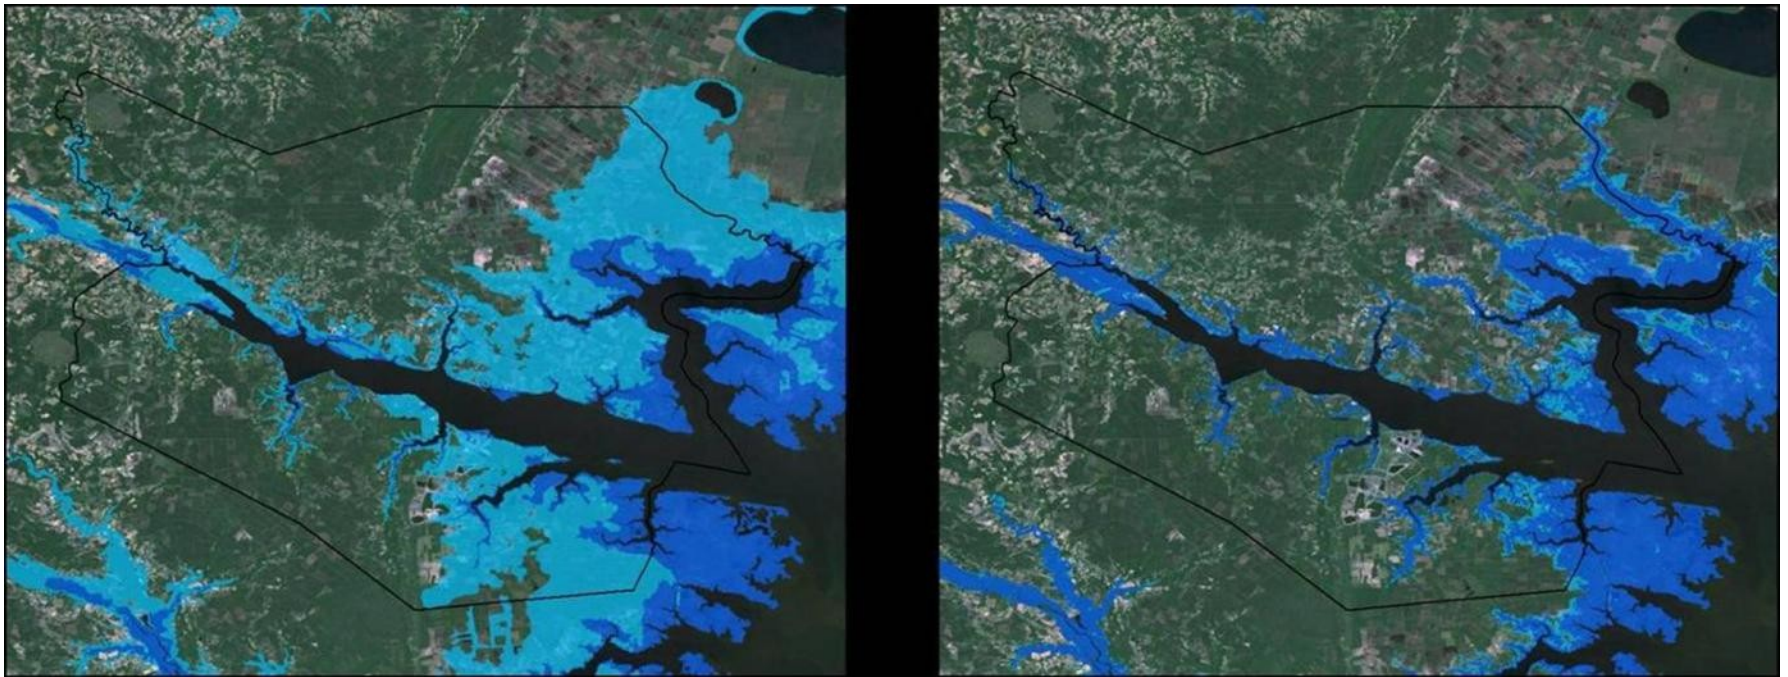

Map Modernization in Texas

	<u>State Total</u>	<u>Current</u>
Number of Counties Mapped	254	126
Percentage	100%	50%
Population in Mapped Counties	24,300,000	22,900,000
Percentage	100%	94%
Area of Counties Mapped (sq mi)	264,708	119,448
Percentage	100%	45%

Terrain data accuracy matters

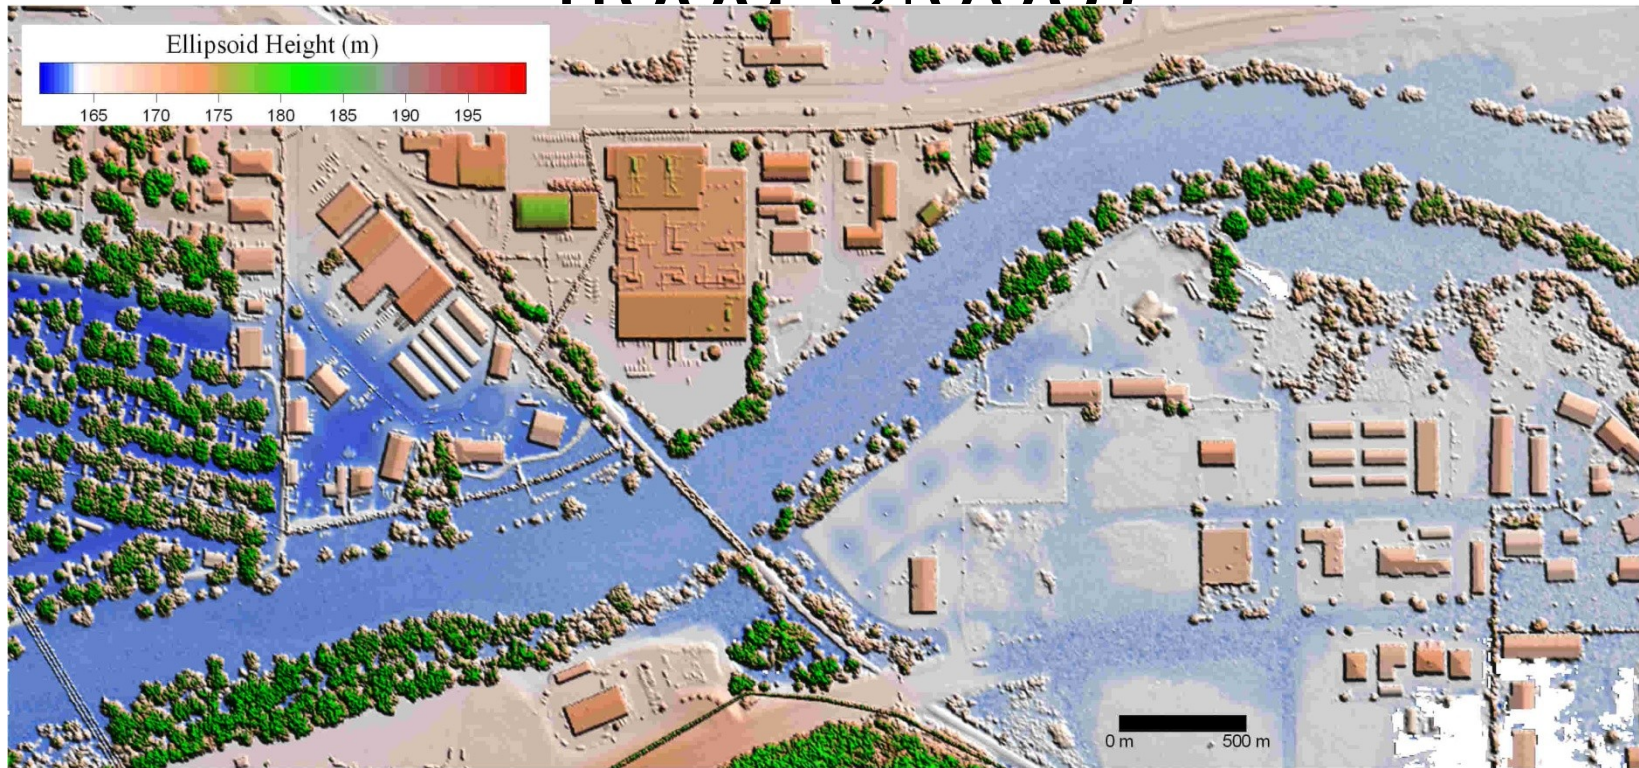

USGS NED (30m)

NCFMP Lidar (3m)

Inundation for a 1ft storm surge or sea level rise in the Tar-Pamlico estuary (Source:

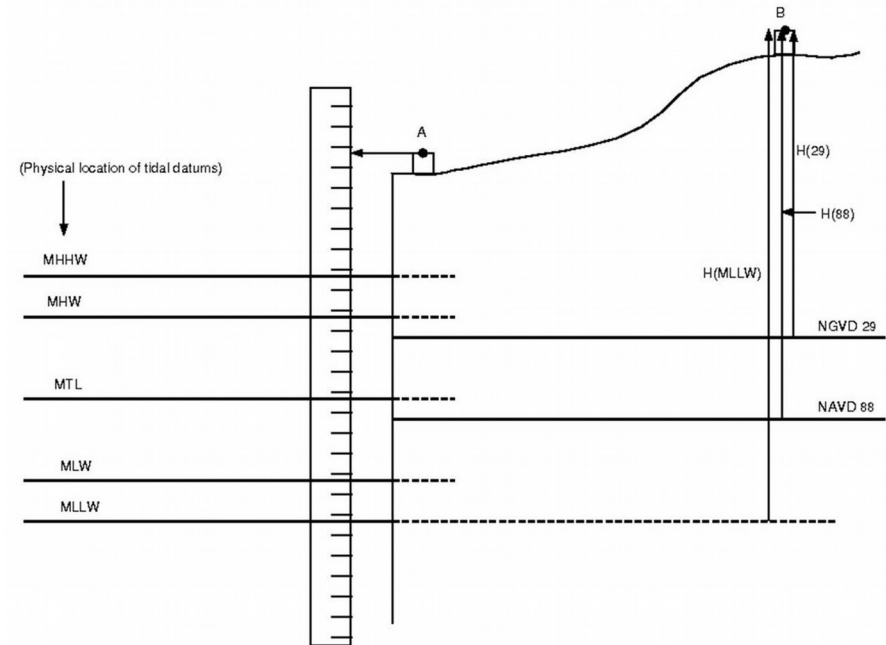

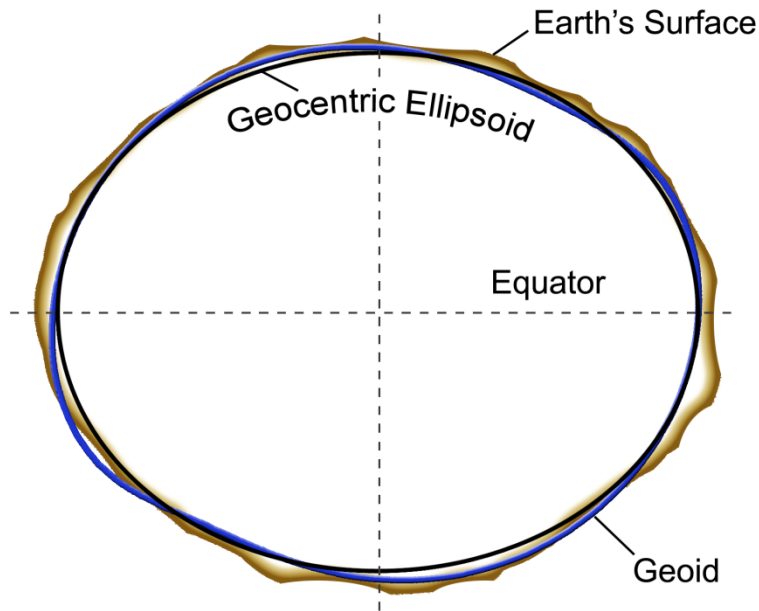

Lidar of inundated water surface elevation during Iowa flood (2008)

Source: University of Iowa and National Center for Airborne Laser Mapping

Three systems for measuring elevation

Orthometric heights (land surveys, geoid) **Ellipsoidal** heights (lidar, GPS) **Tidal** heights (Sea water level)

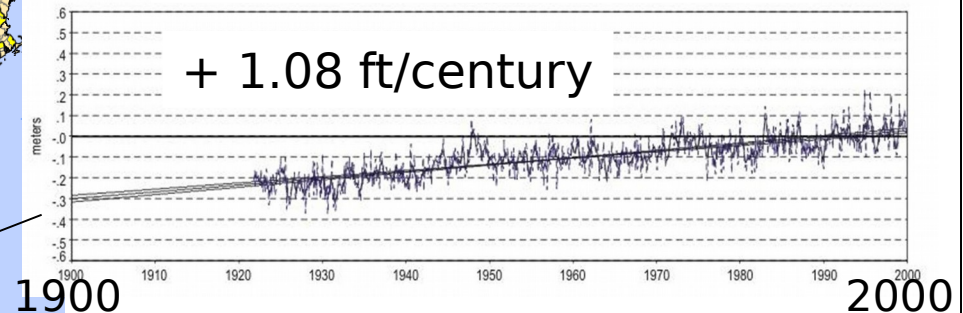

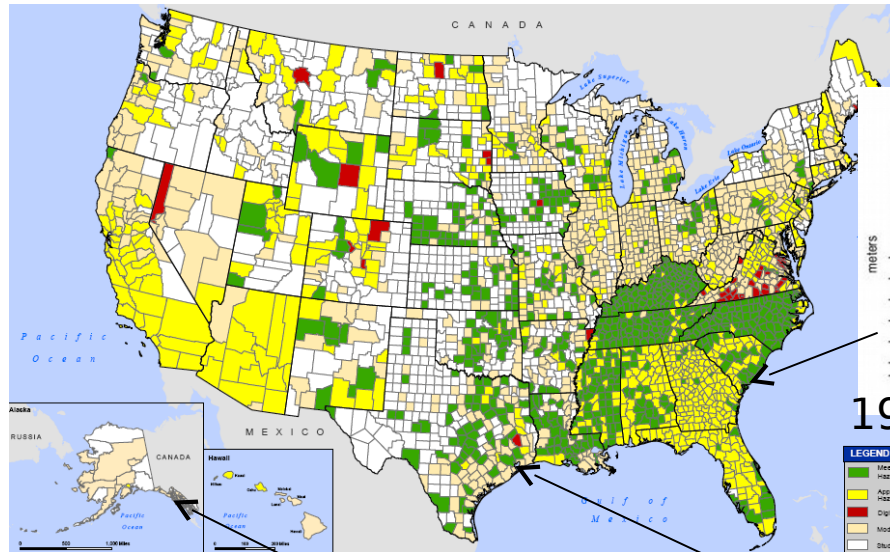

Improved reconciliation of these three systems is needed

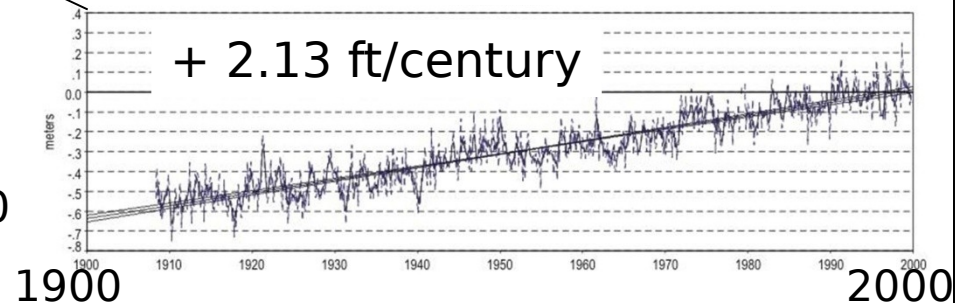

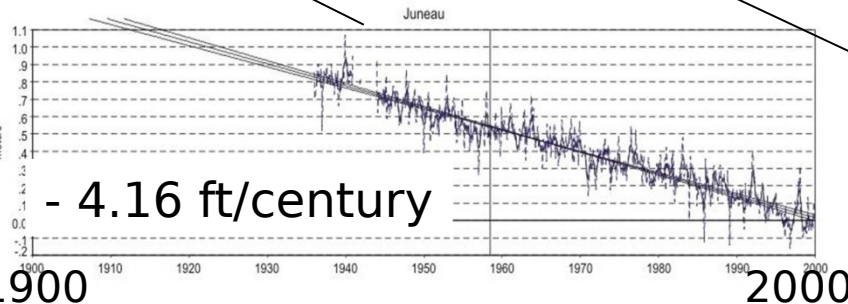

Trends in Tide Levels

(coastal flood risk is changing)

Charleston, SC

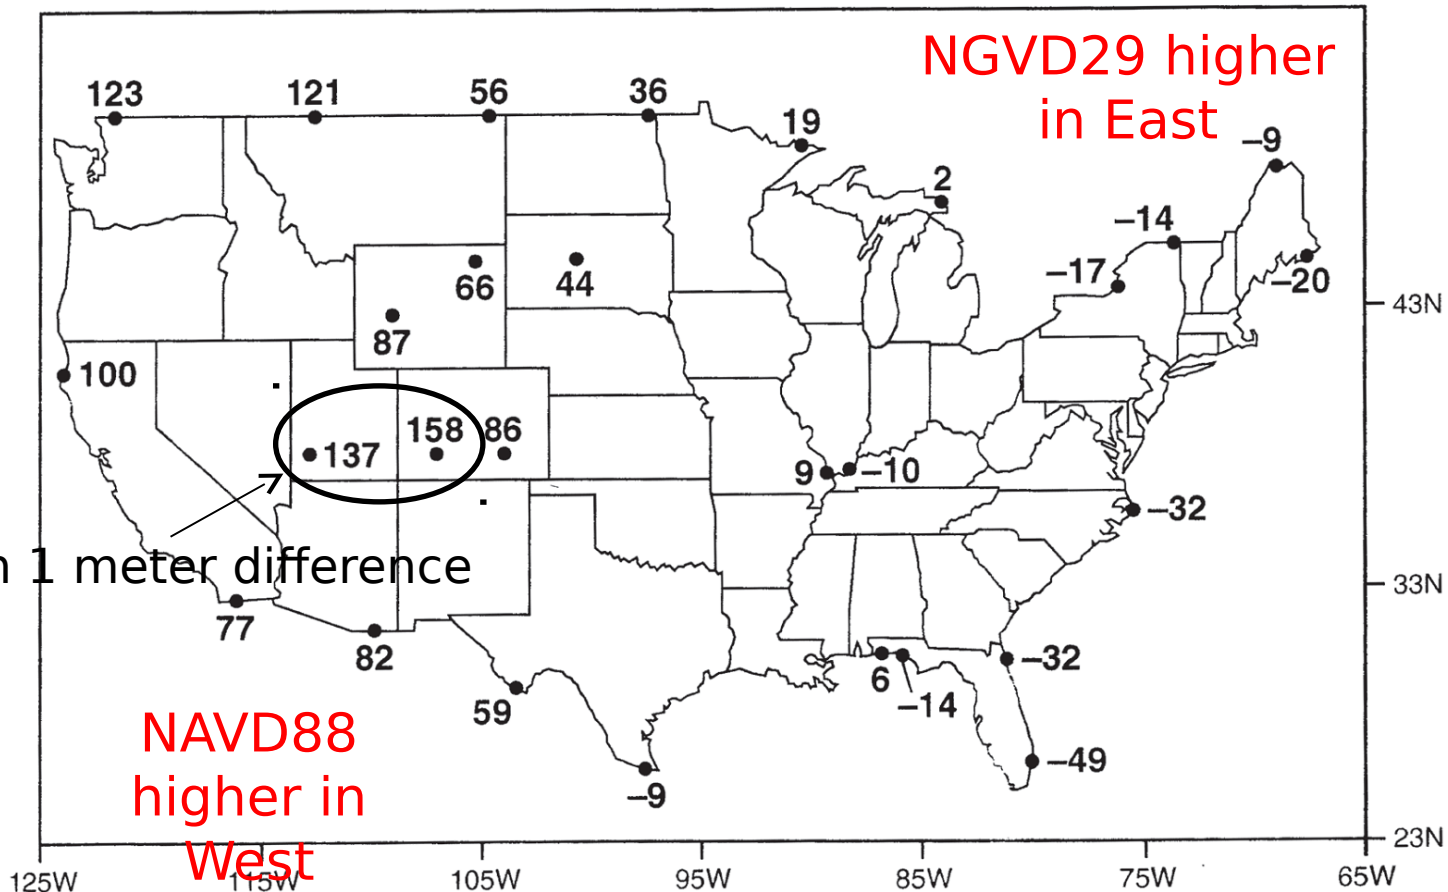

Galveston, TX

Juneau, AK

Importance of geodetic datums

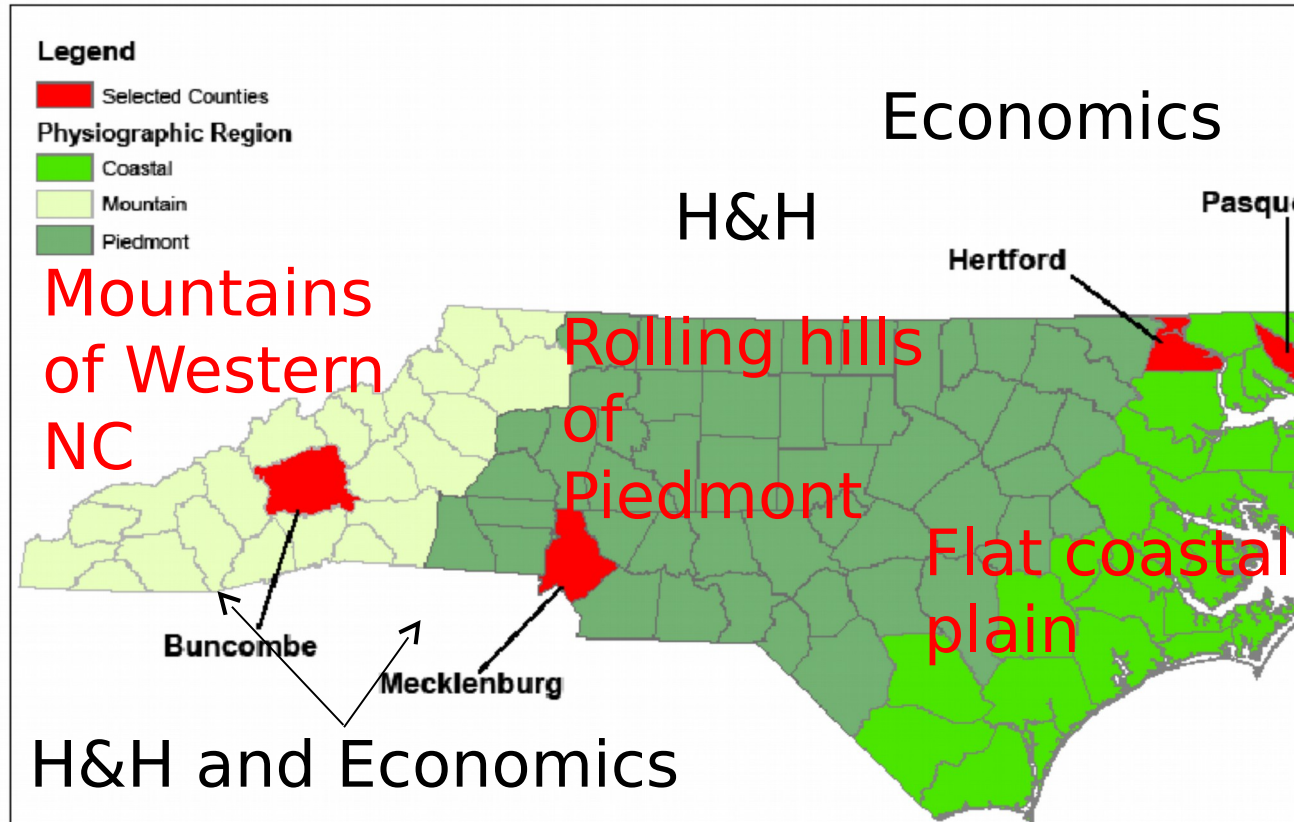

Orthometric datum height shifts are significant relative to BFE accuracy, so standardization on NAVD88 is justified

North Carolina Case Studies

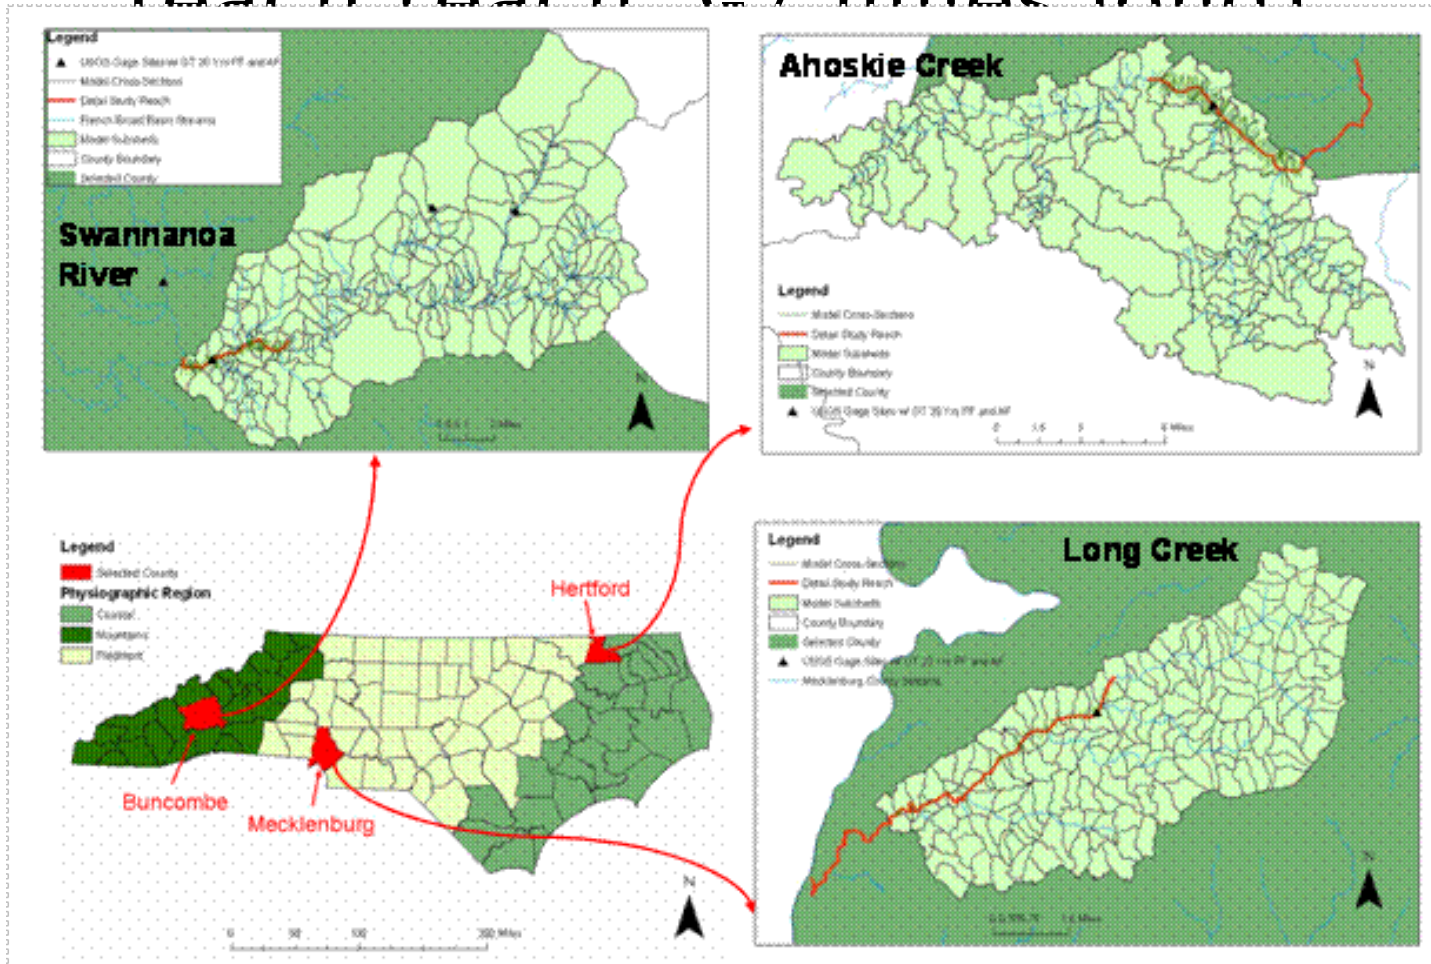

<http://www.m>

Studies done for the NRC Committee by the North Carolina Floodplain Mapping Program (NCFMP)

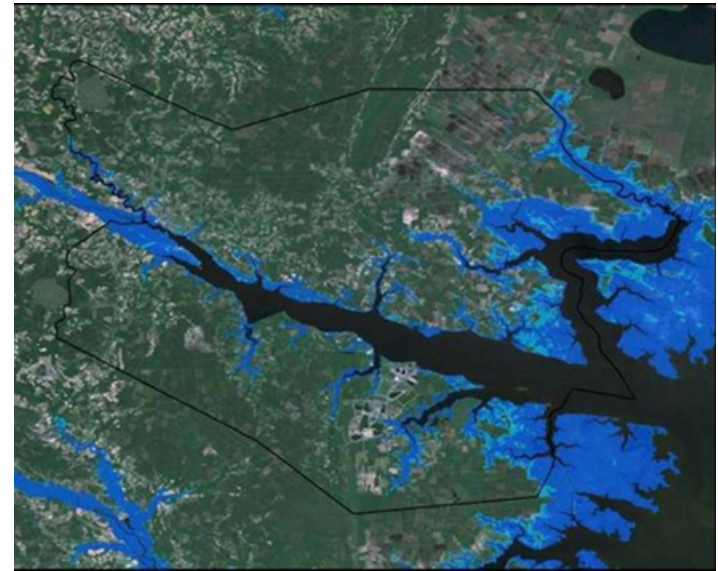

(H&H = Hydrology and Hydraulics)

One River Reach studied in detail in each region (each reach 5-7 miles long)

Terrain Data for Case Studies

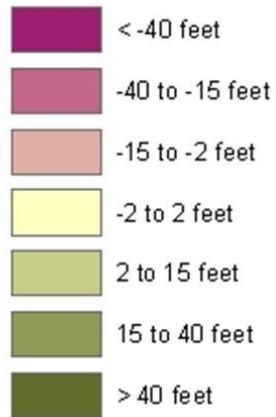

USGS DEMs (30m)

NCFPM Lidar (3m)

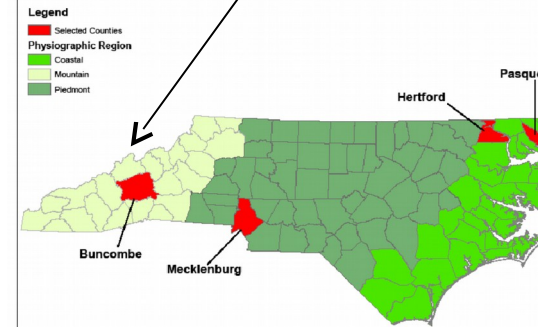

Swannanoa River, Buncombe County, NC

NED - Lidar

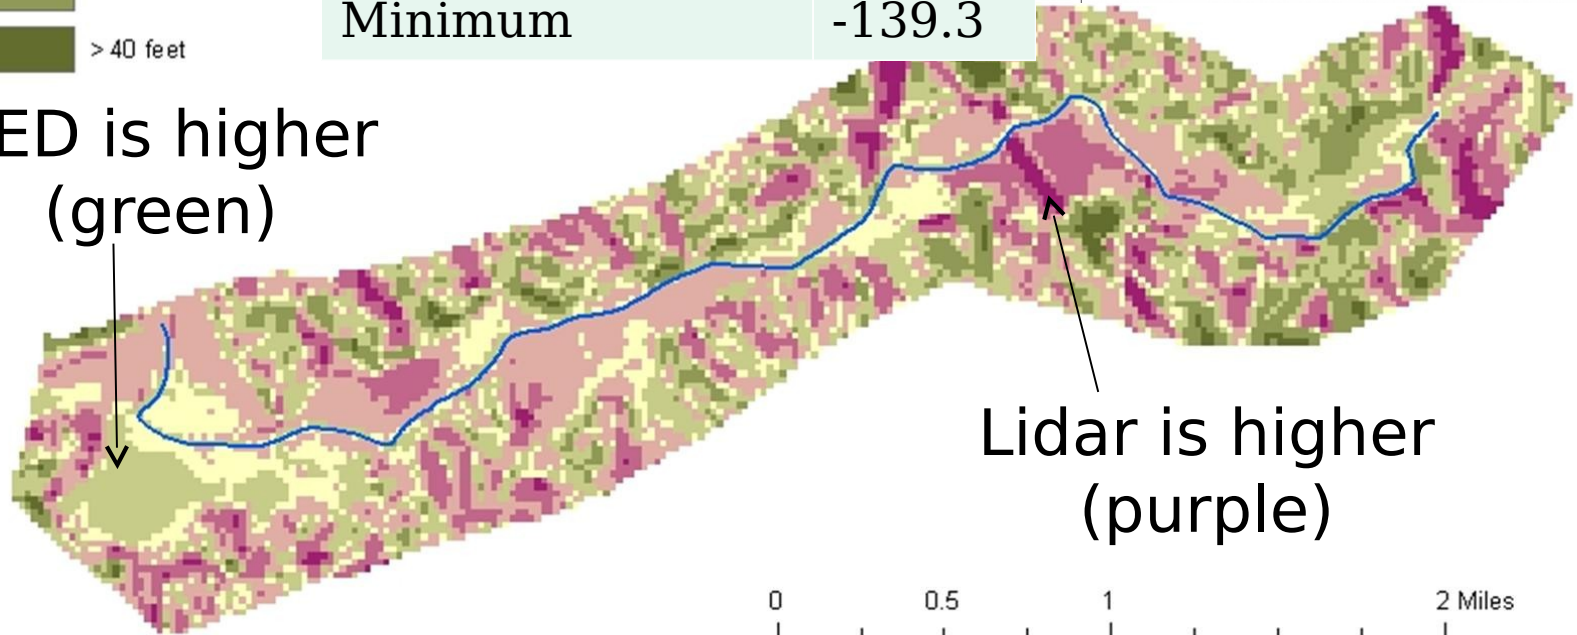

Elevation Difference

NED - Lidar	Feet
Mean	-2.0
Standard deviation	17.5
Maximum	89.7
Minimum	-139.3

NED is higher
(green)

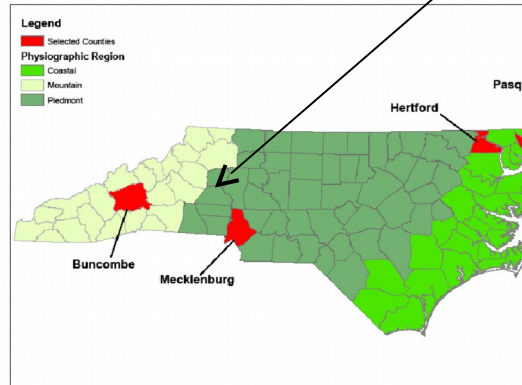

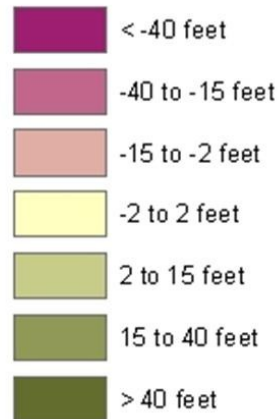

Lidar is higher

(green)

NED - Lidar	Feet
Mean	14.7
Standard deviation	15.6
Maximum	81.5
Minimum	- 46.0

An elevation "bust"
Systematic and random errors

Ahoskie Creek, Hertford County, NC

Terrain Data

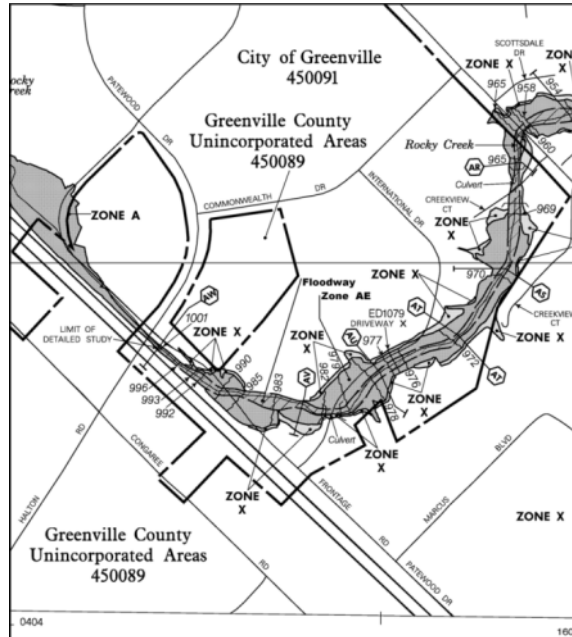

- Our study demonstrates that there are large differences between LIDAR and NED
 - Random differences everywhere
 - Systematic differences in some places

Presentation Outline

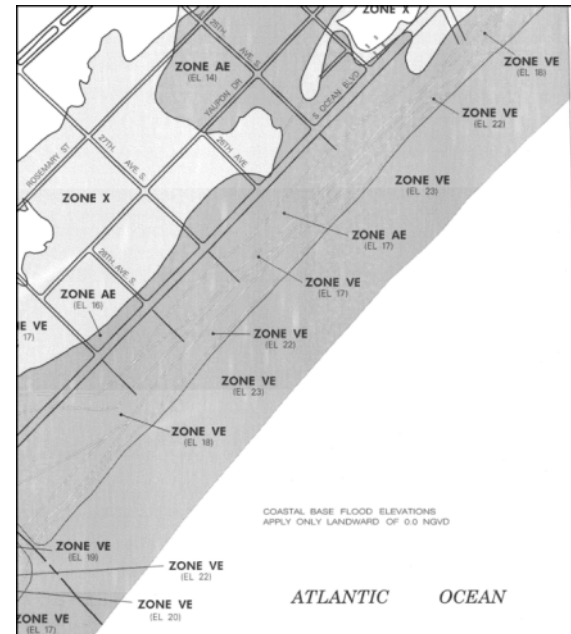

- Overview of Committee Charge
- Review of Elevation for Floodplain mapping study
- *Mapping the Zone Report Chapters*
 - 1-3 Overview of flood mapping and terrain data
 - 4-5 Inland and Coastal flood mapping
- Overarching Findings

Flood Maps

Riverine

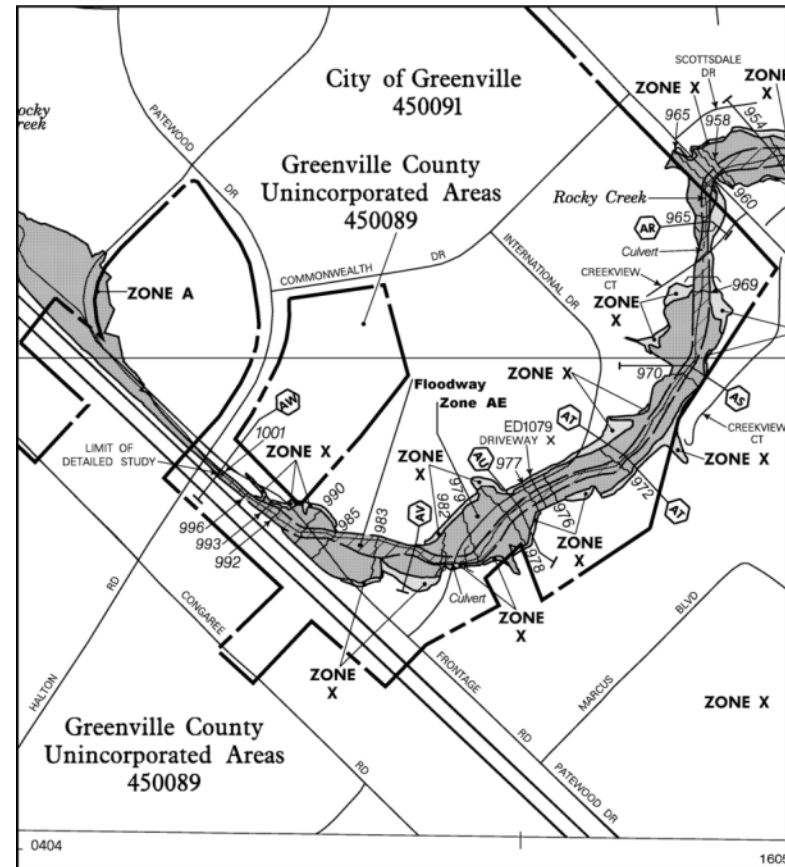

Coastal

Two **very different** flood modeling and mapping problems

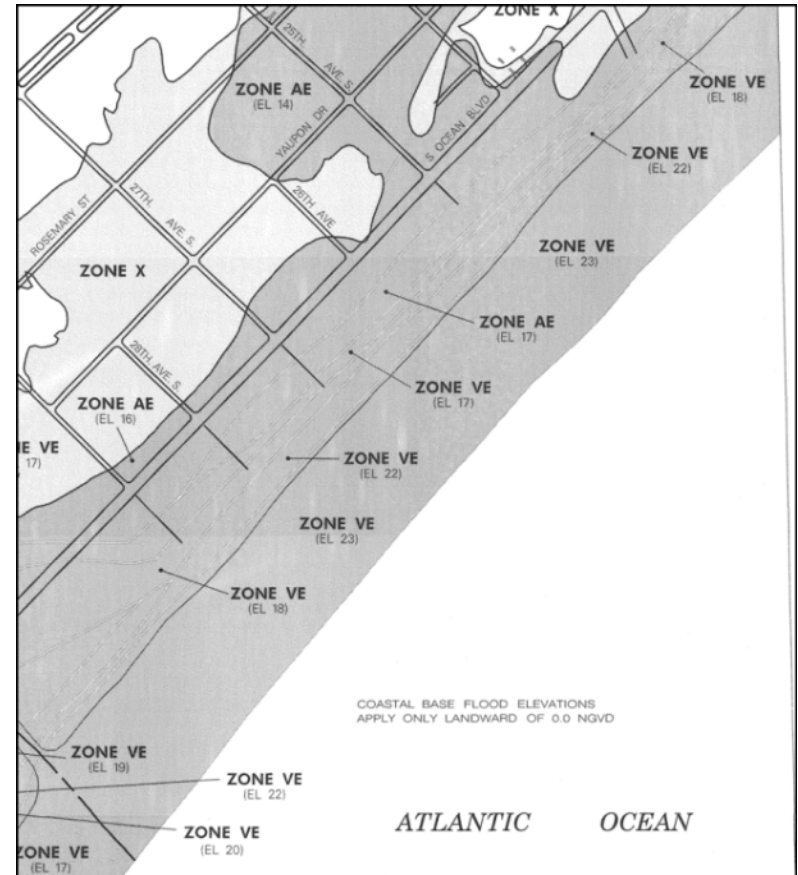

Riverine Flood Mapping

- Modeling and mapping technology is well established
- Supported by a large observation database at stream gages
- Floods flow along the line of the stream gages

Coastal Flood Mapping

- Modeling and mapping technology and guidance are evolving
- Storm surges inland transverse to the line of tide gages
- Large dependence on models, less on historical flood data

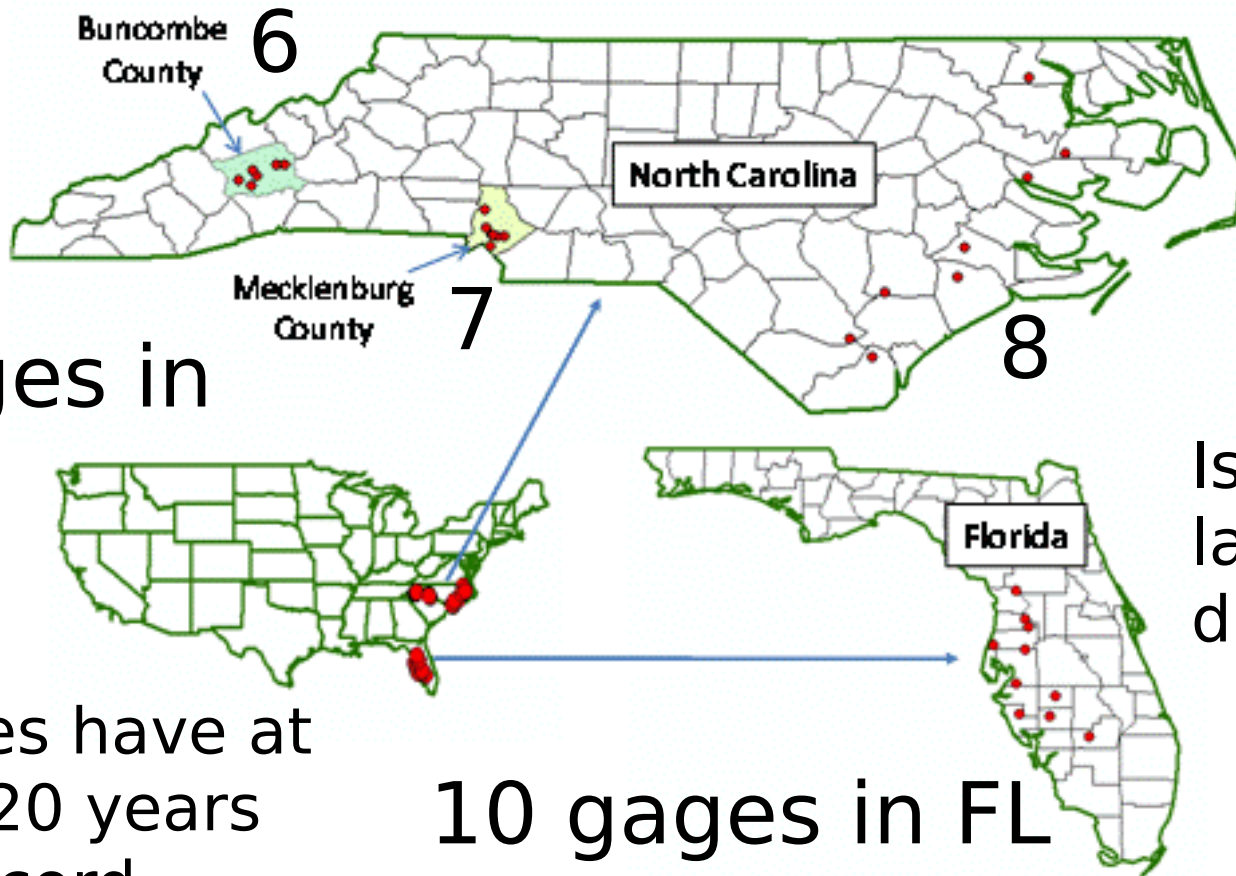

Defining Uncertainty in BFE

Long term records of extreme stages recorded
at USGS gages

At each gage the peak **stage** is recorded for each year along with the peak **flow** – do a frequency analysis of these.

Frequency Analysis of Stage Heights at 31 gages

21 gages in NC

All gages have at least 20 years record

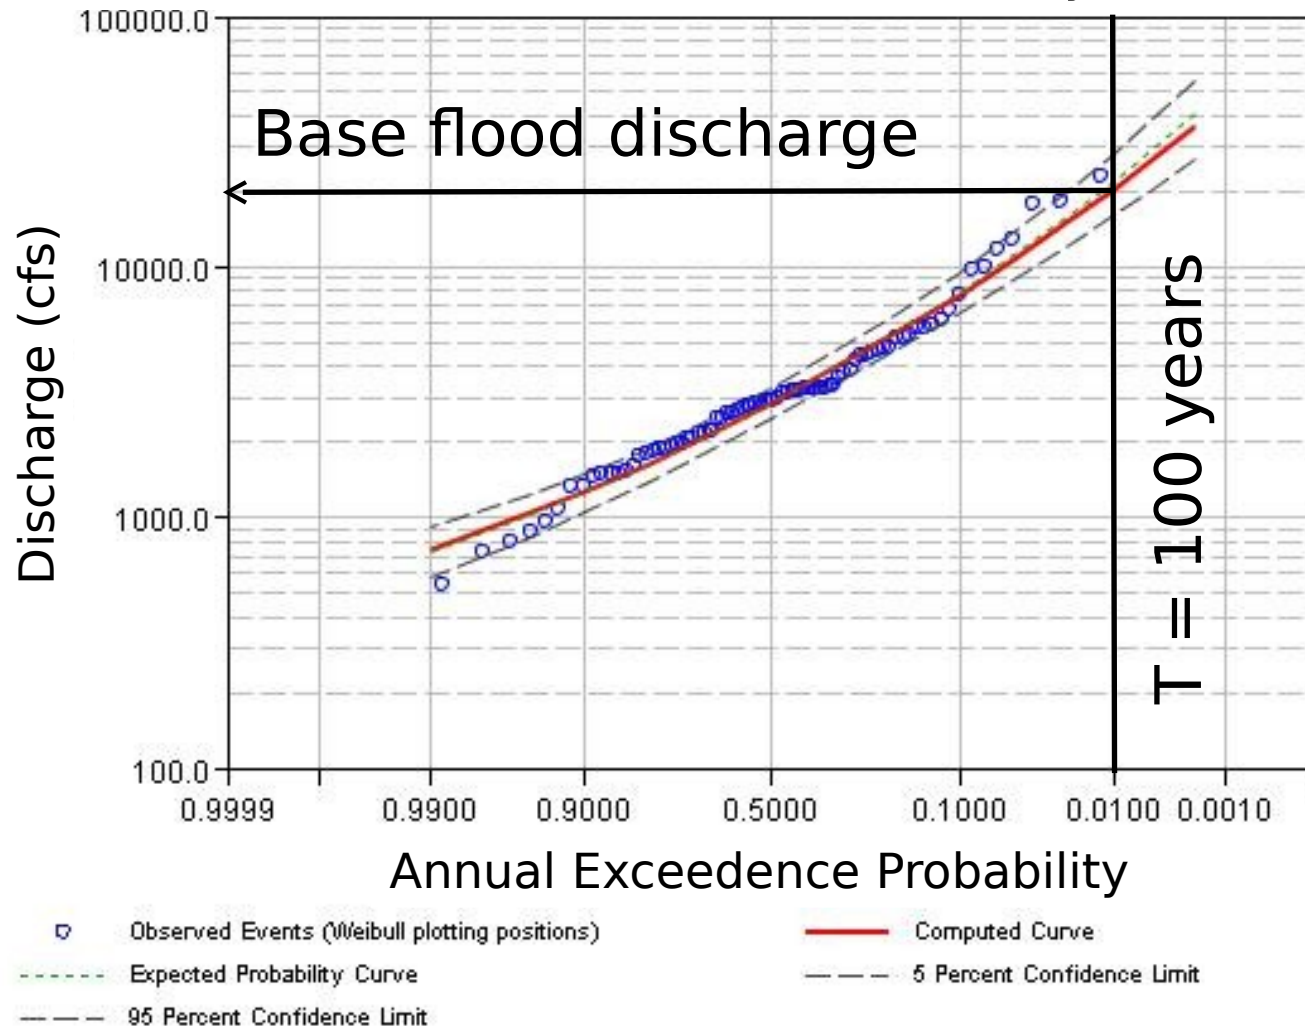

Is pitted FL landscape different?

10 gages in FL

THE NATIONAL ACADEMIES
Advisers to the Nation on Science, Engineering, and Medicine

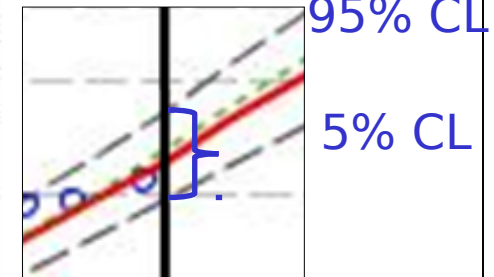

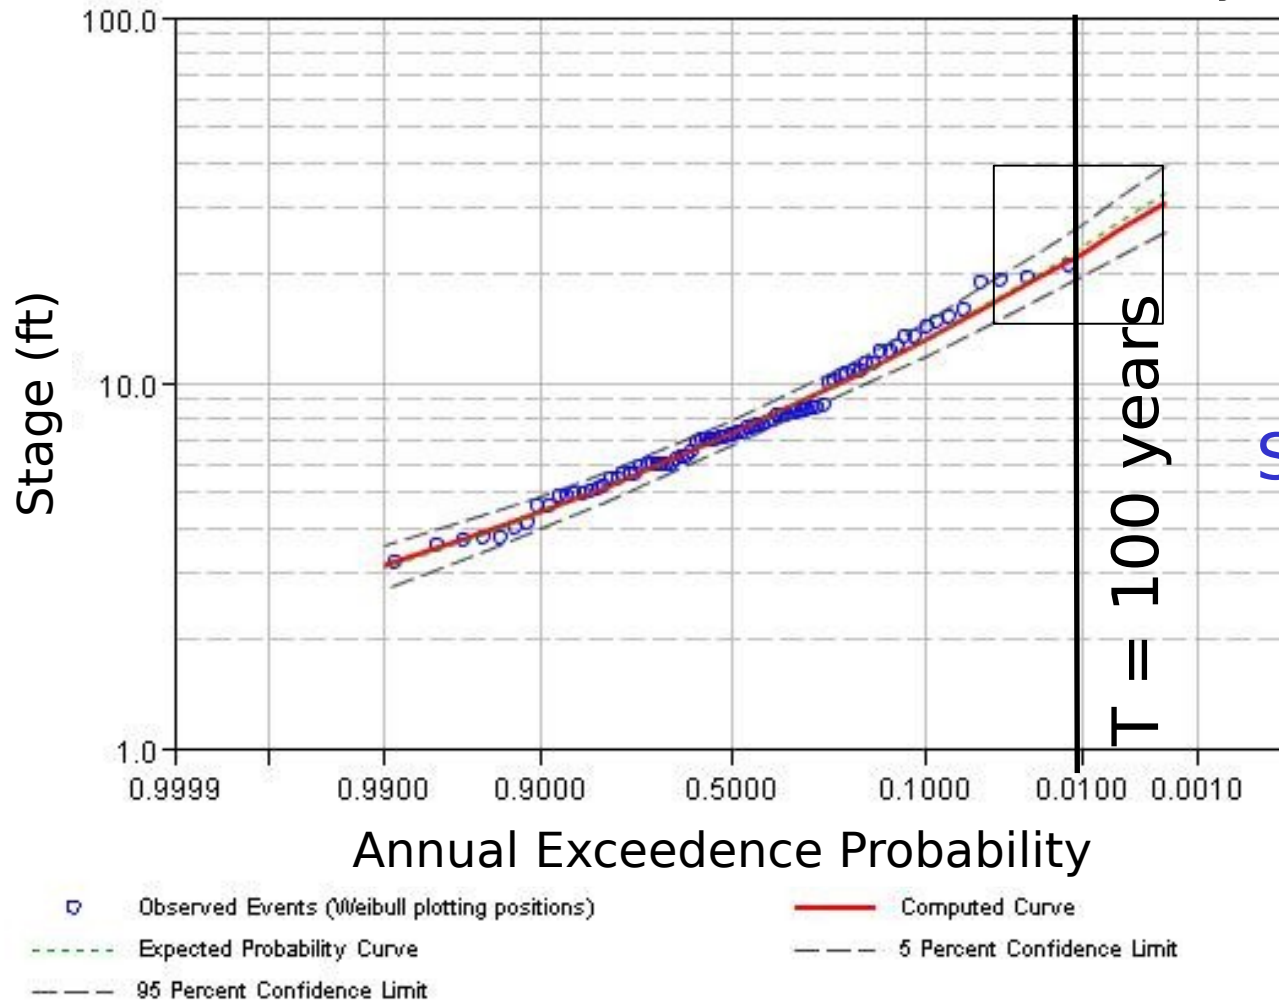

Science, Engineering,
years)

Swannanoa River at Biltmore, NC (78 years of record)

Produced using the Corps HEC-SSP Program
(Bulletin 17-B standard procedure)

Swannanoa River at Biltmore, NC (78 years of record)

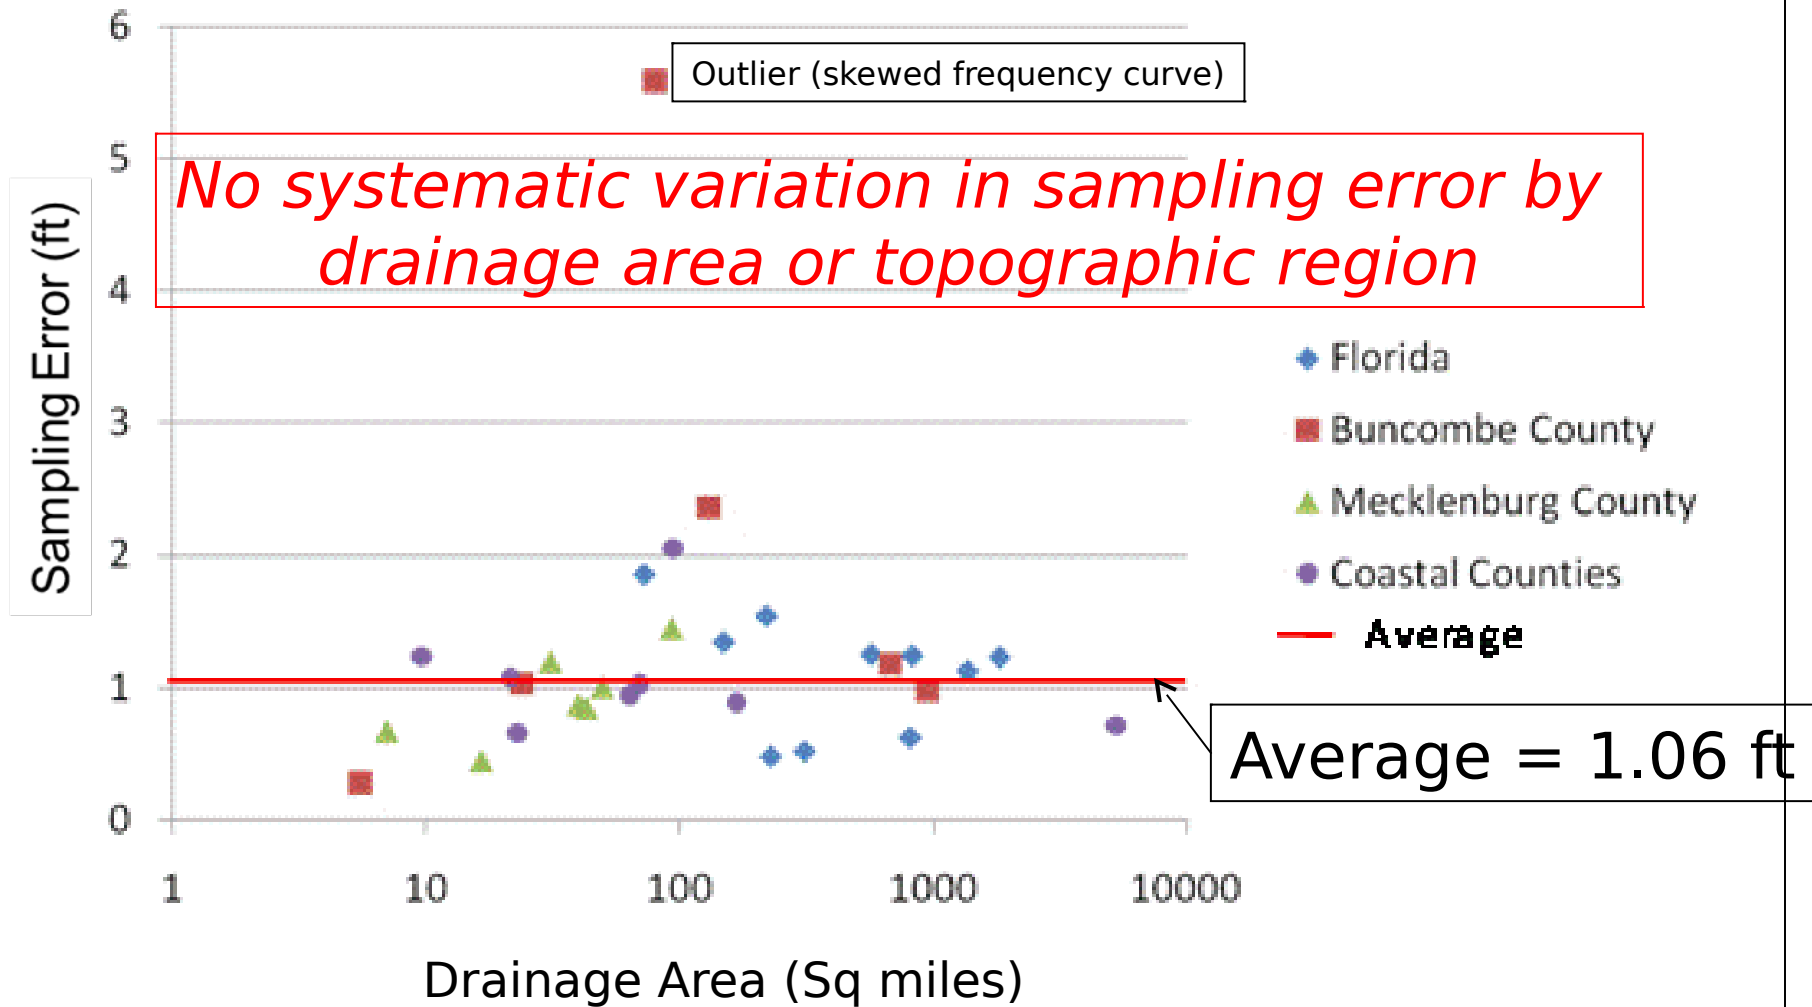

Sampling error =

$$\frac{95\%CL - 5\%CL}{3.29}$$

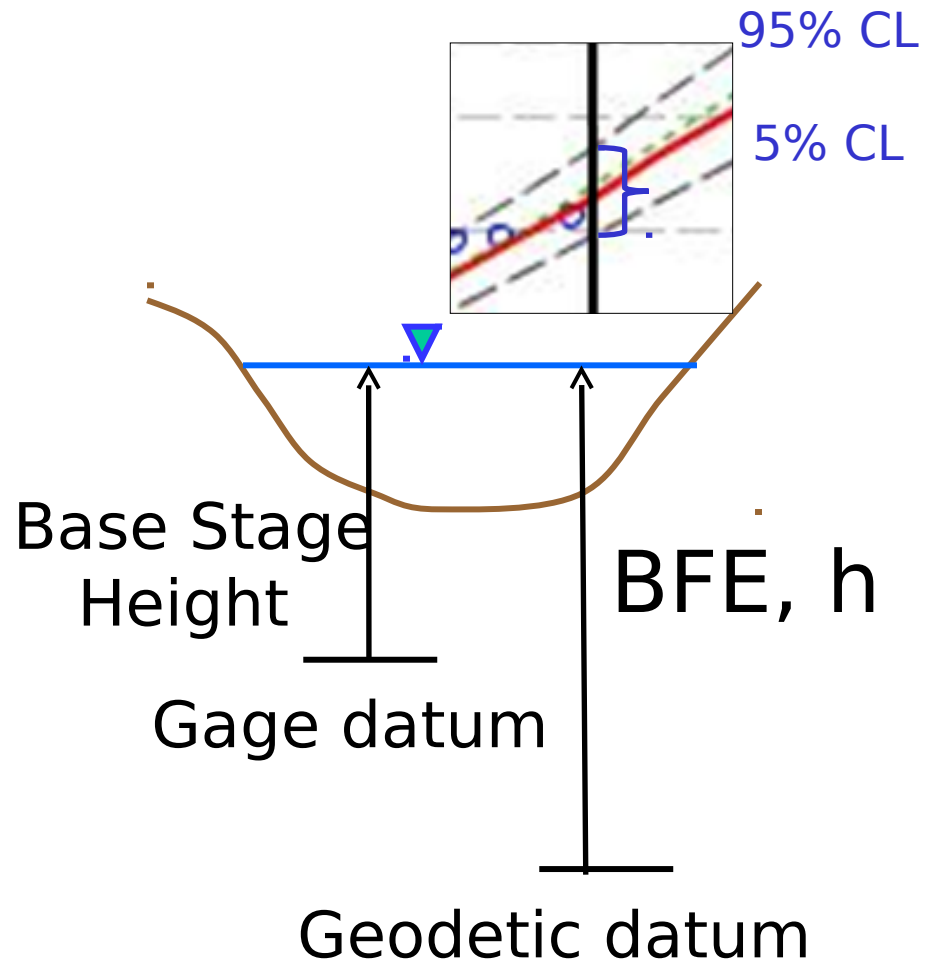

Uncertainty in BFE = Uncertainty in 100-year stage height

Sampling Error of 100-year Stage Heights

Uncertainty in BFE

- BFE and Base Stage Height differ by a constant amount (gage datum – geodetic datum)
- This doesn't affect uncertainty of **statistical variation** of sample data around the 100-year estimate
- Average value of sample error at 30 of 31 gage sites is 1.06 ft
- ***A Lower Bound on the uncertainty of the BFE is a standard error of estimate of approximately one foot***

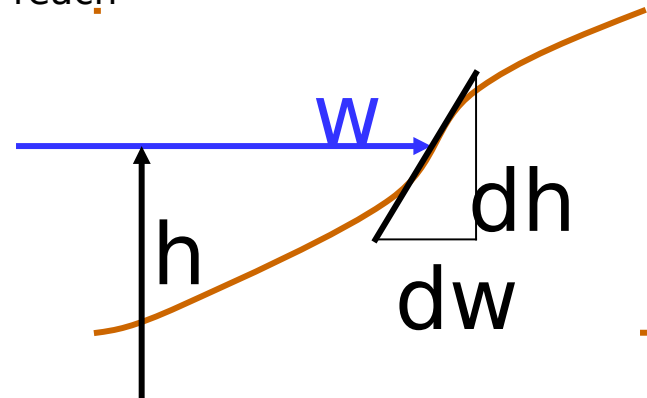

Uncertainty in Floodplain Boundary Location

$$dw/dh = \text{Run/Rise}$$

County	Lateral slope (%)	Run/rise (ft)
Ahoskie Creek	2.4	42
Long Creek	9.8	10
Swannanoa River	12.9	8

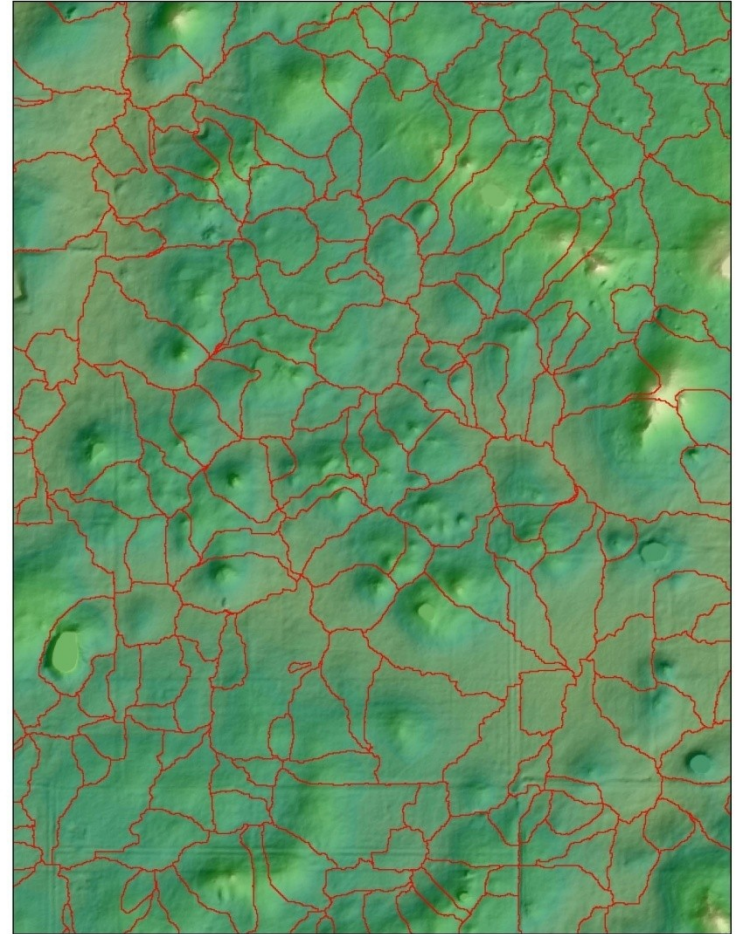

Lateral channel slope is calculated on HEC-RAS cross-sections at the point of intersection of water surface with land surface (left and right banks) and averaged for all cross-sections in the reach

A Lower Bound on the uncertainty of the floodplain boundary location ranges from approximately 8ft in the mountains to approximately 40 ft in the coastal plain

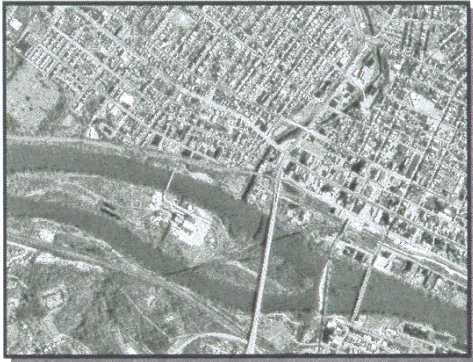

Interconnected Ponds (e.g. Florida)

- Gage study showed that BFE uncertainty in Florida rivers is similar to NC
- Many complex hydrologic issues inherent in how water reaches river from a ponded landscape
- *Needs a separate study*

DEFINITIONS

STORM EFFECTS

540 sq ft RULE

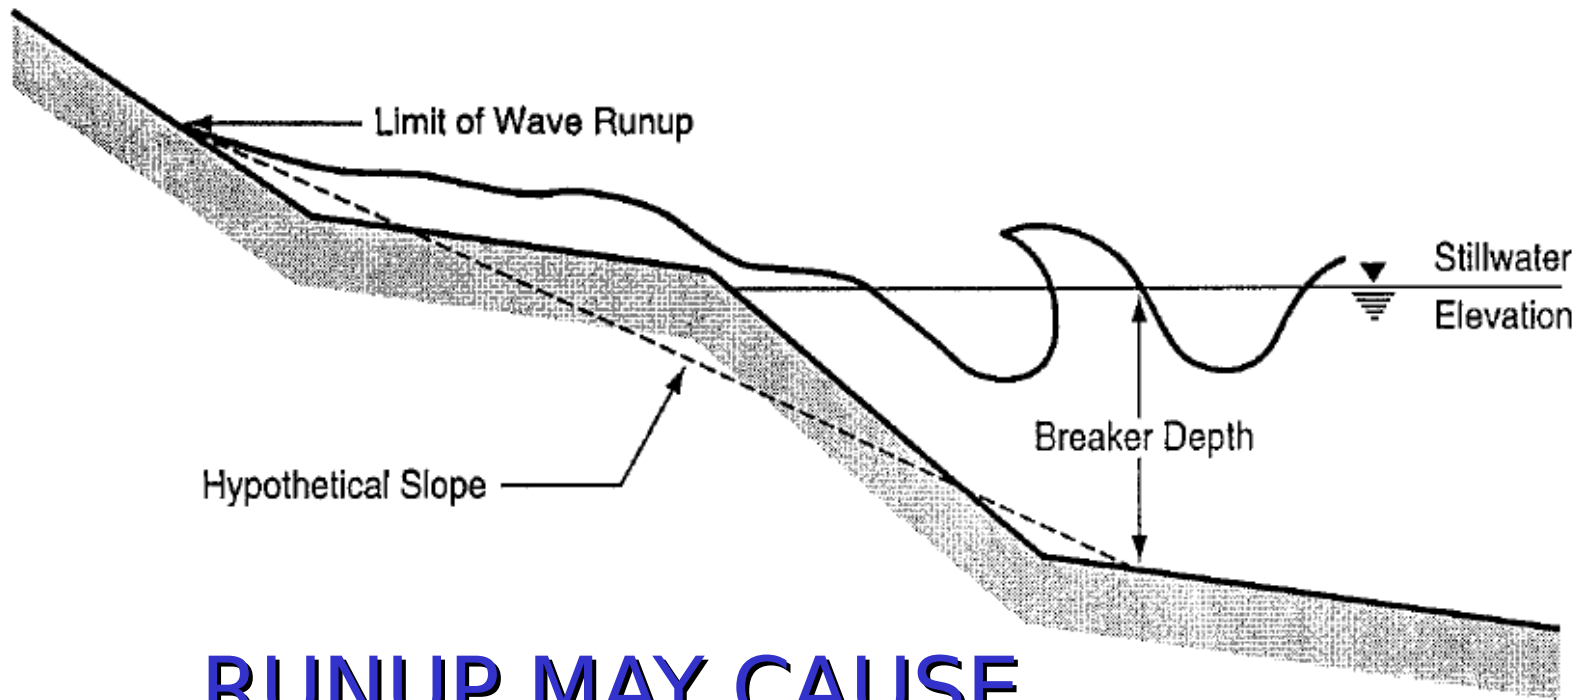

Eliminates the dune if
volume of sand above
stillwater elevation is
insufficient to impede waves

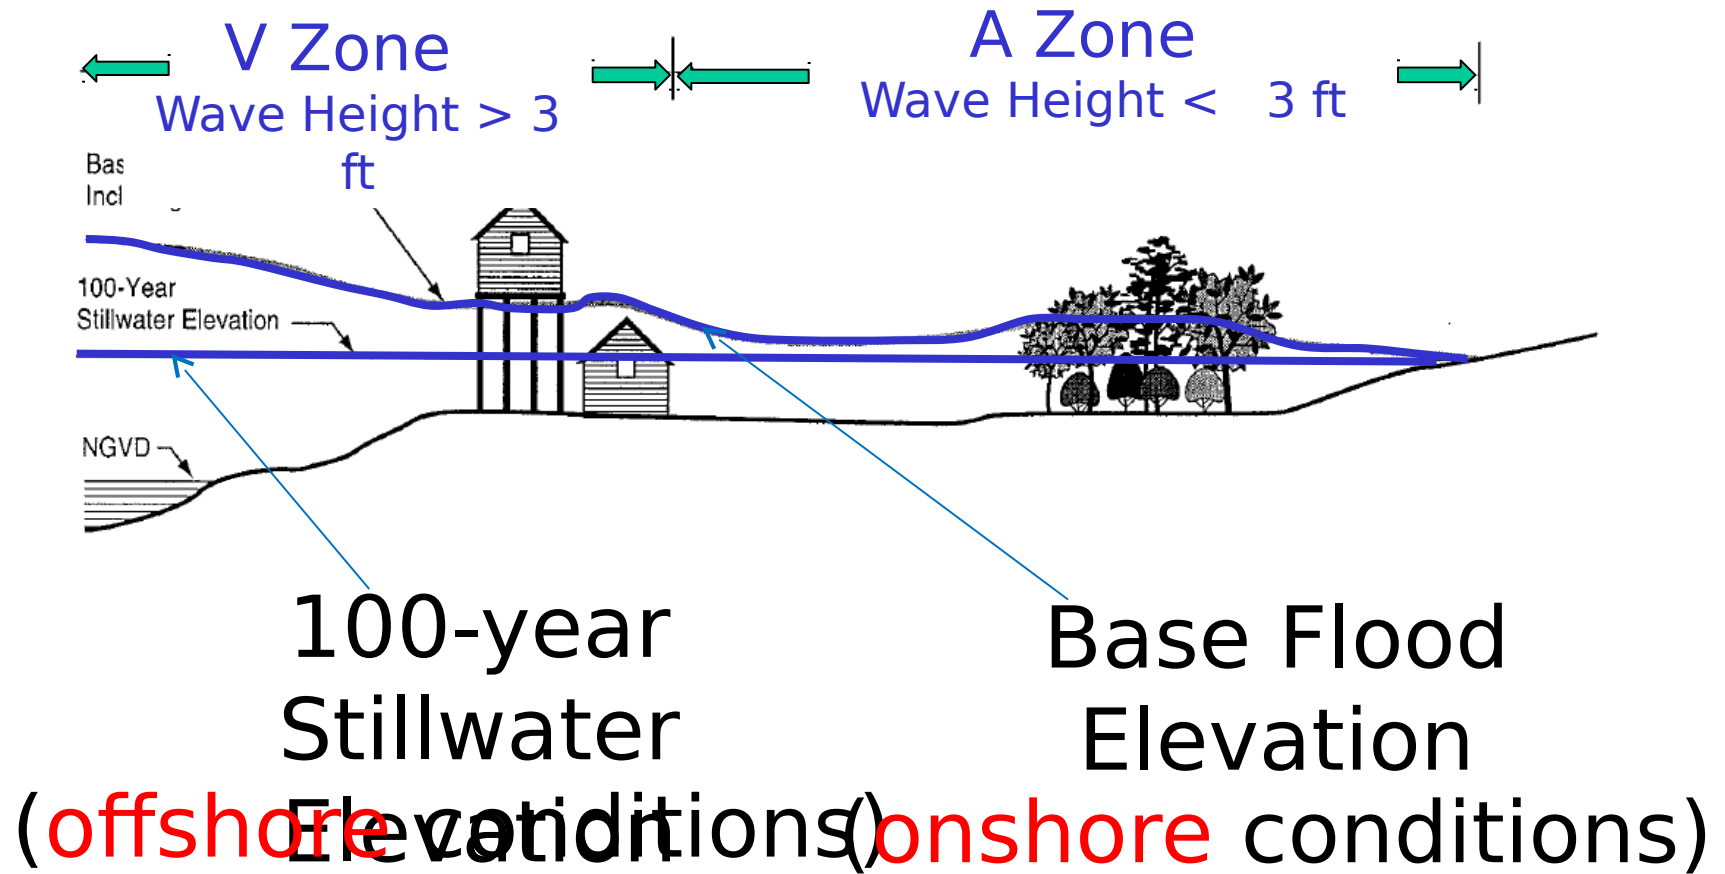

THE NATIONAL ACADEMIES
Advisers to the Nation on Science, Engineering, and Medicine

WAVE RUNUP

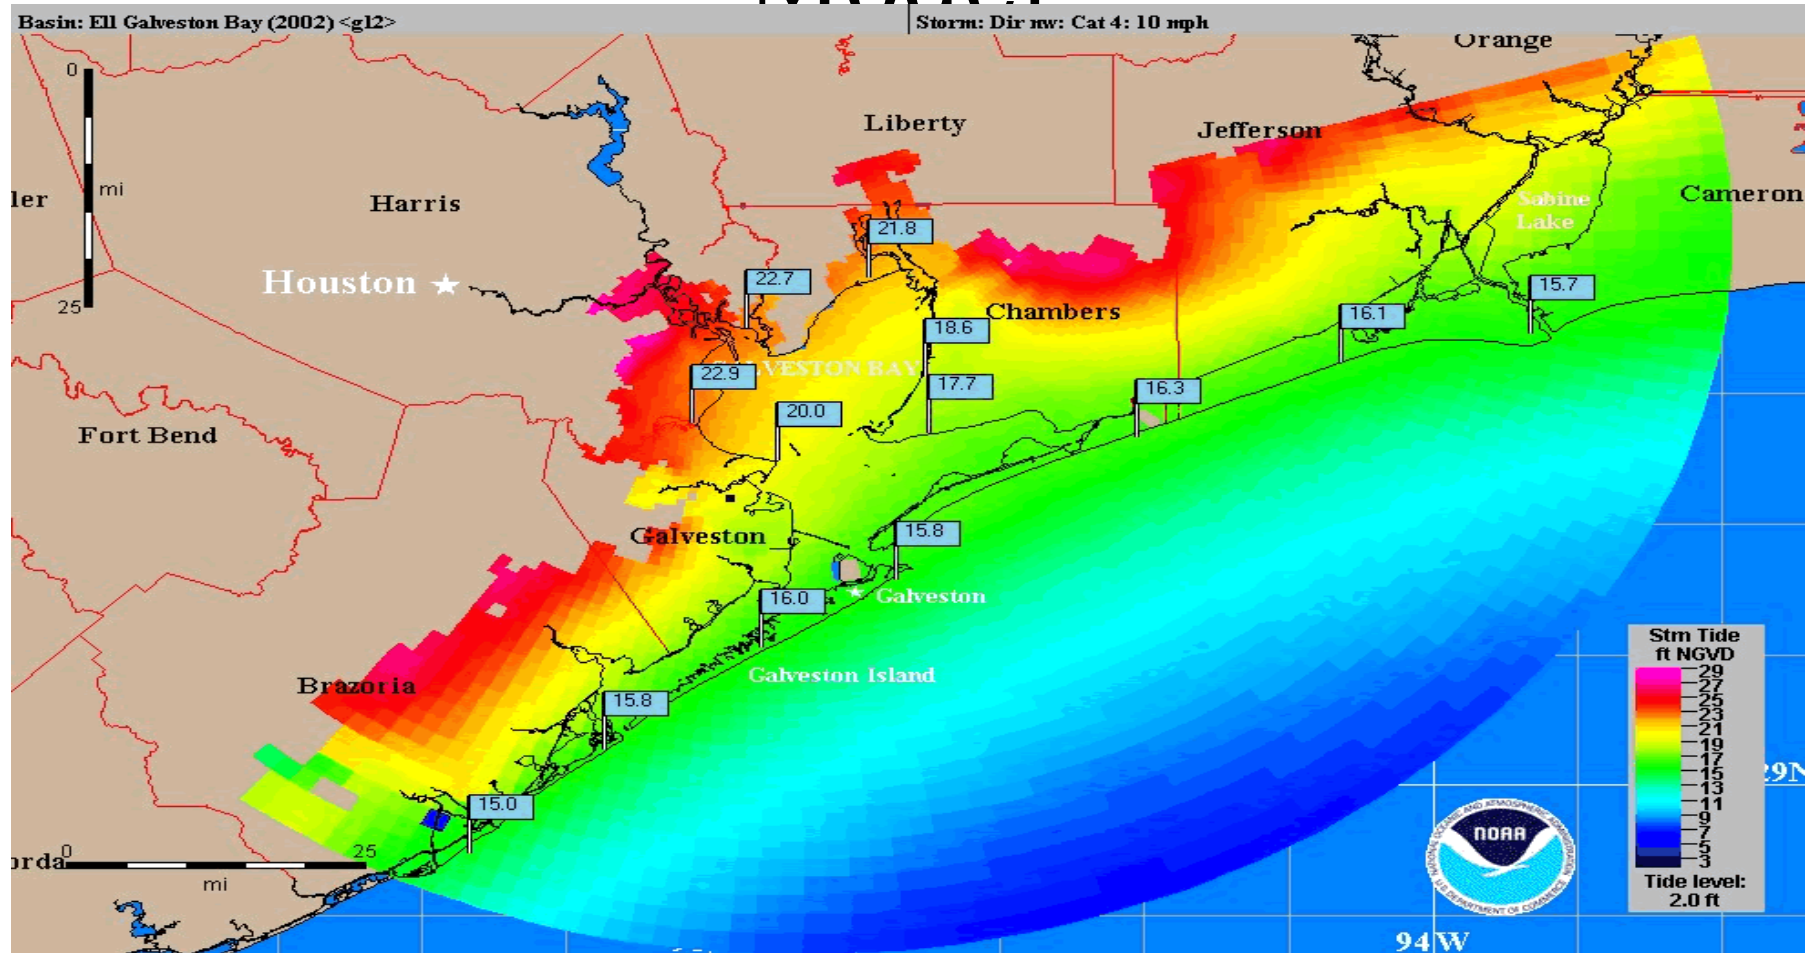

**RUNUP MAY CAUSE
OVERTOPPING**

Coastal Flood Elevations

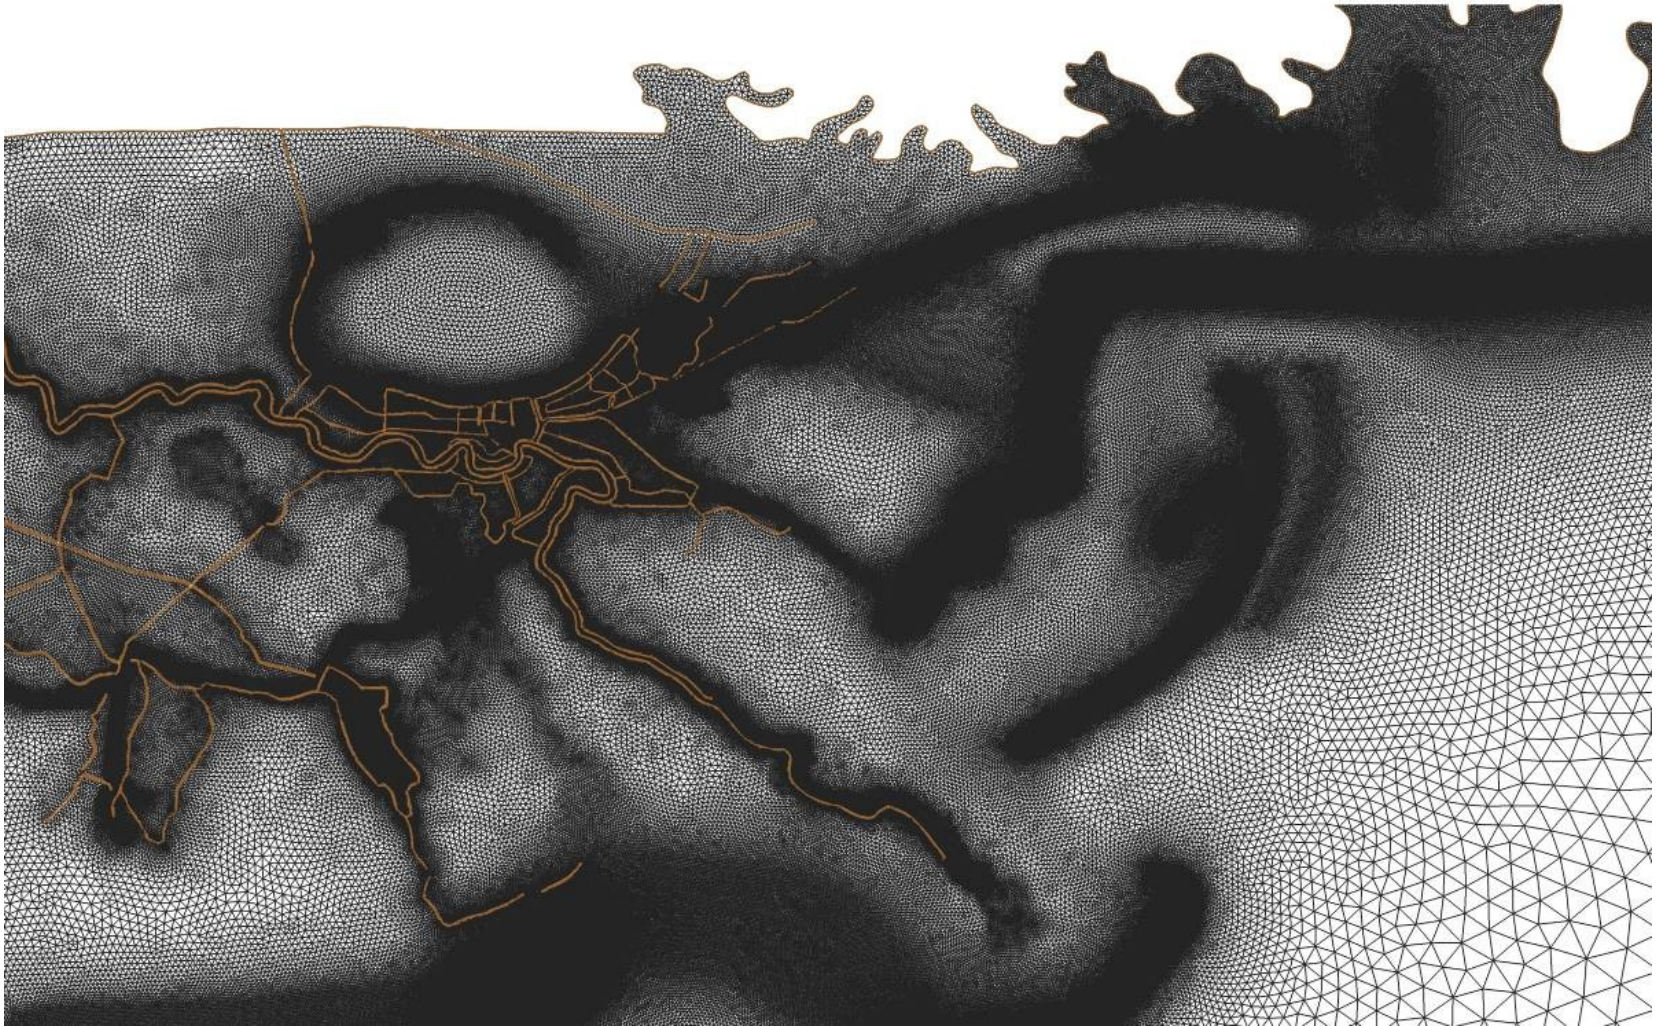

SLOSH - NOAA Storm Surge Model

Storm: Cat. 4 moving NW at 10mph

ADCIRC (Advanced CIRCulation)

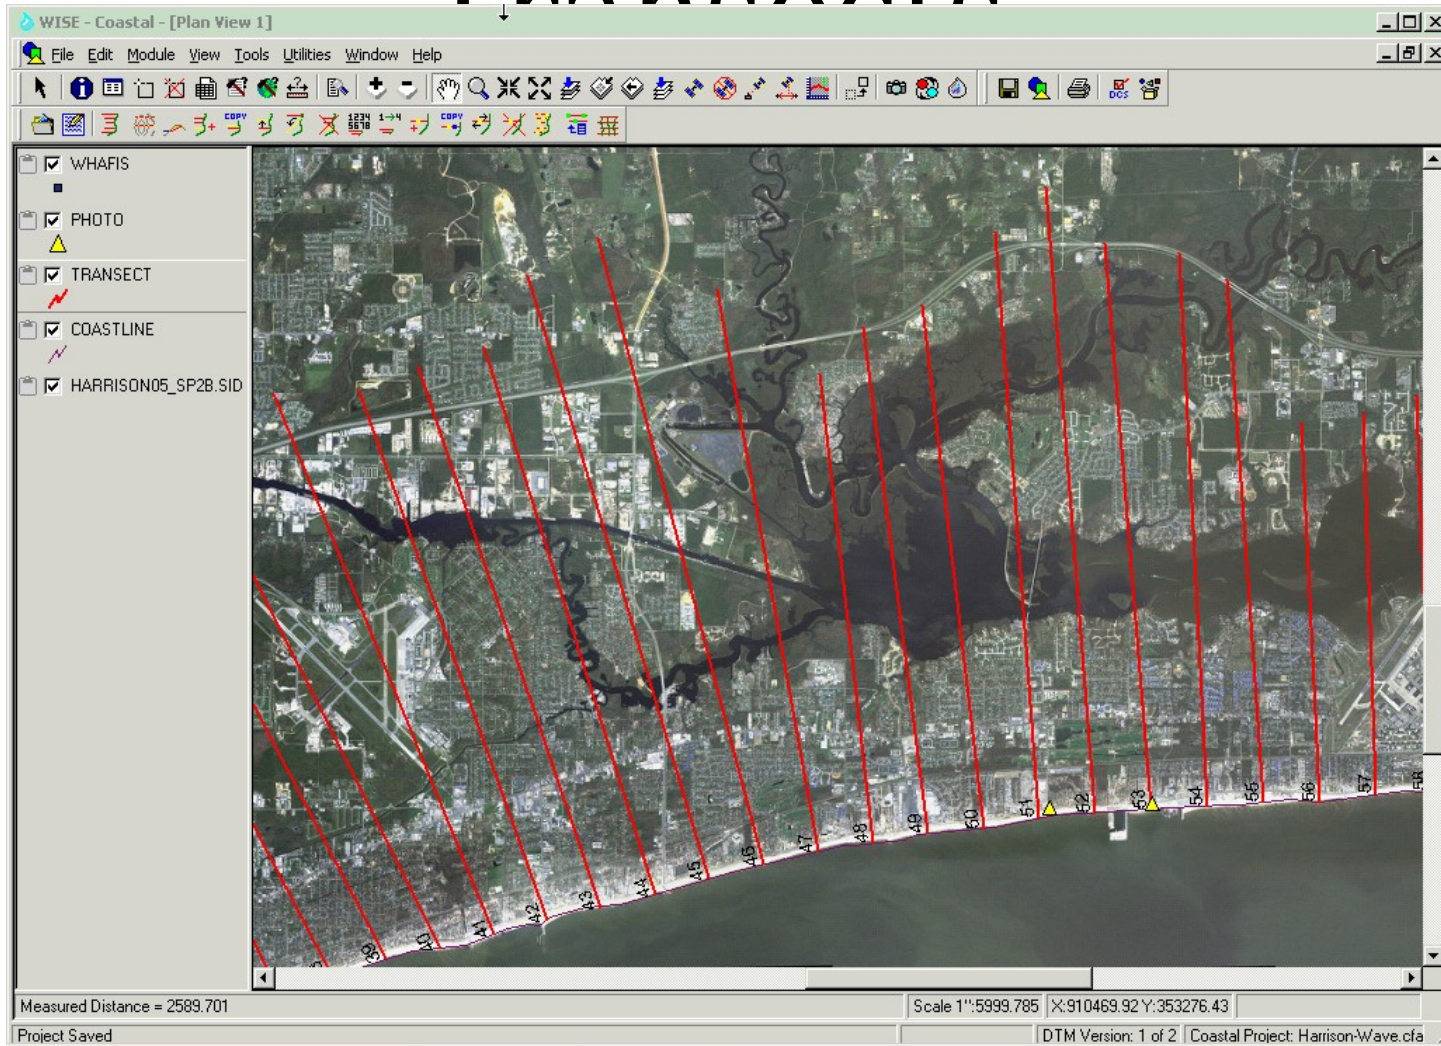

Finite element model, used by USACE for Gulf Coast

Storm Simulation

- **Storm surge** is affected by wind, atm pressure, bathymetry, tide, wave, topography, etc.
- **Tides** in the Gulf of Mexico are 2-3 ft in amplitude. Along the Atlantic coast, tides increase from 2-3 ft in FL to 20 ft in Canada.
- **Waves** are generally lower in Gulf Coast due to gentler slope.
- Factors affecting accuracy of storm surge simulation:
 - **Input data** (wind, bathymetry, topography, etc.)
 - **Model dimensionality**, domain, grid resolution
 - **Model processes**, parameterization, and coefficients
 - Wave-current interaction (2D, 3D, one-way, two-way)
 - Surge-tide interaction
 - Marshes, barrier islands, buildings, levees
 - Manning's n for bottom friction, air-sea drag coefficient
 - Precipitation and riverine flow
 - Erosion

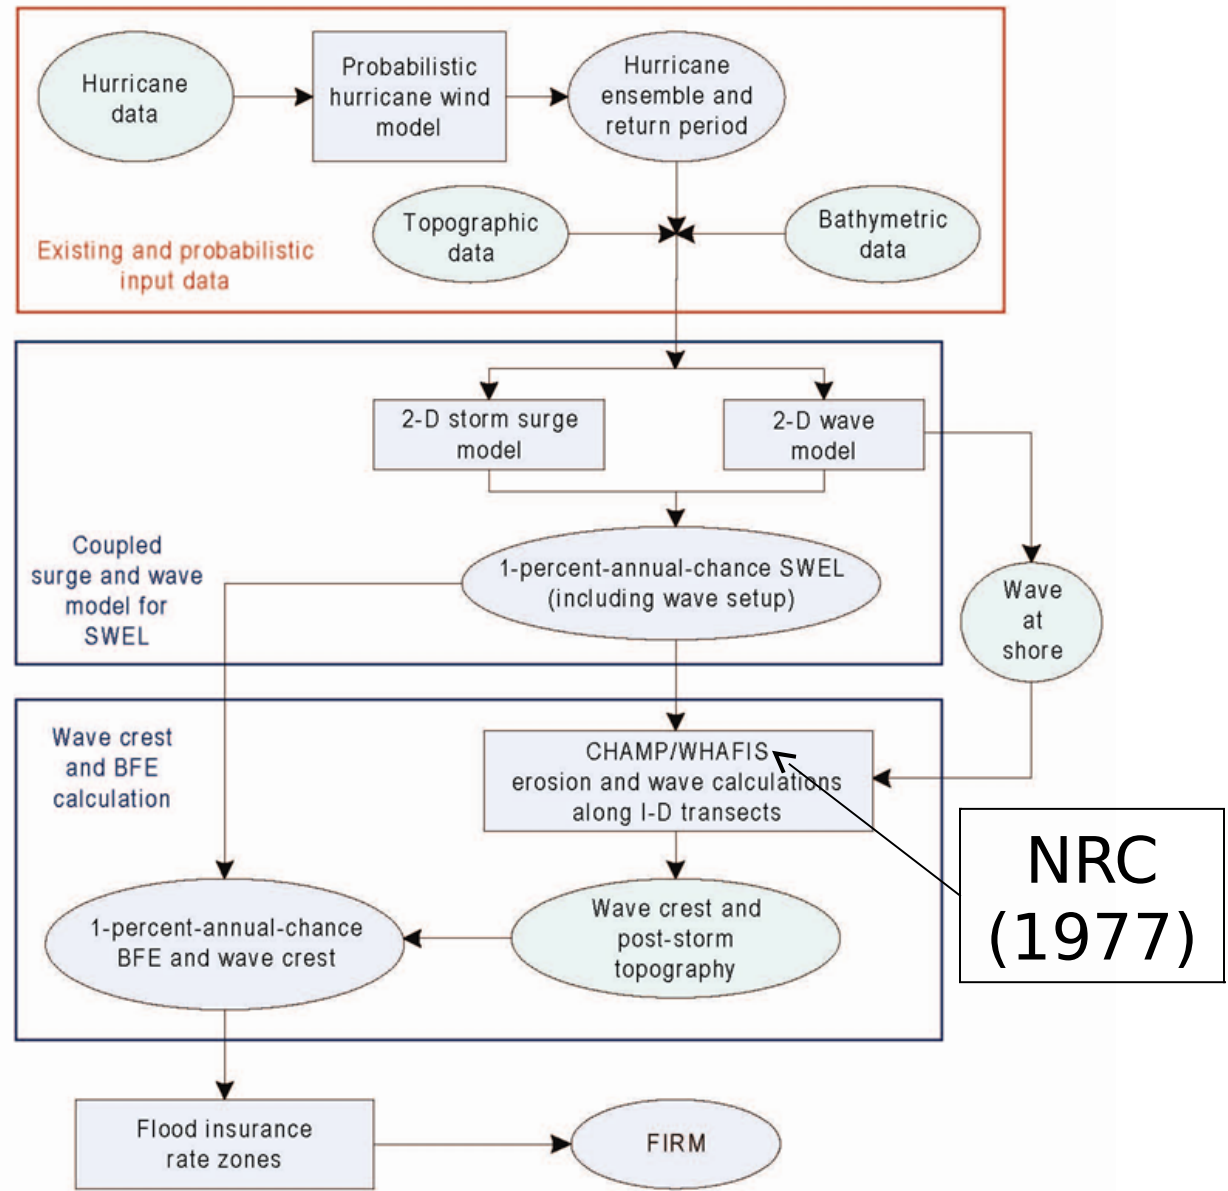

Coastal Flood Mapping

Transects

Current coastal flood mapping methodology

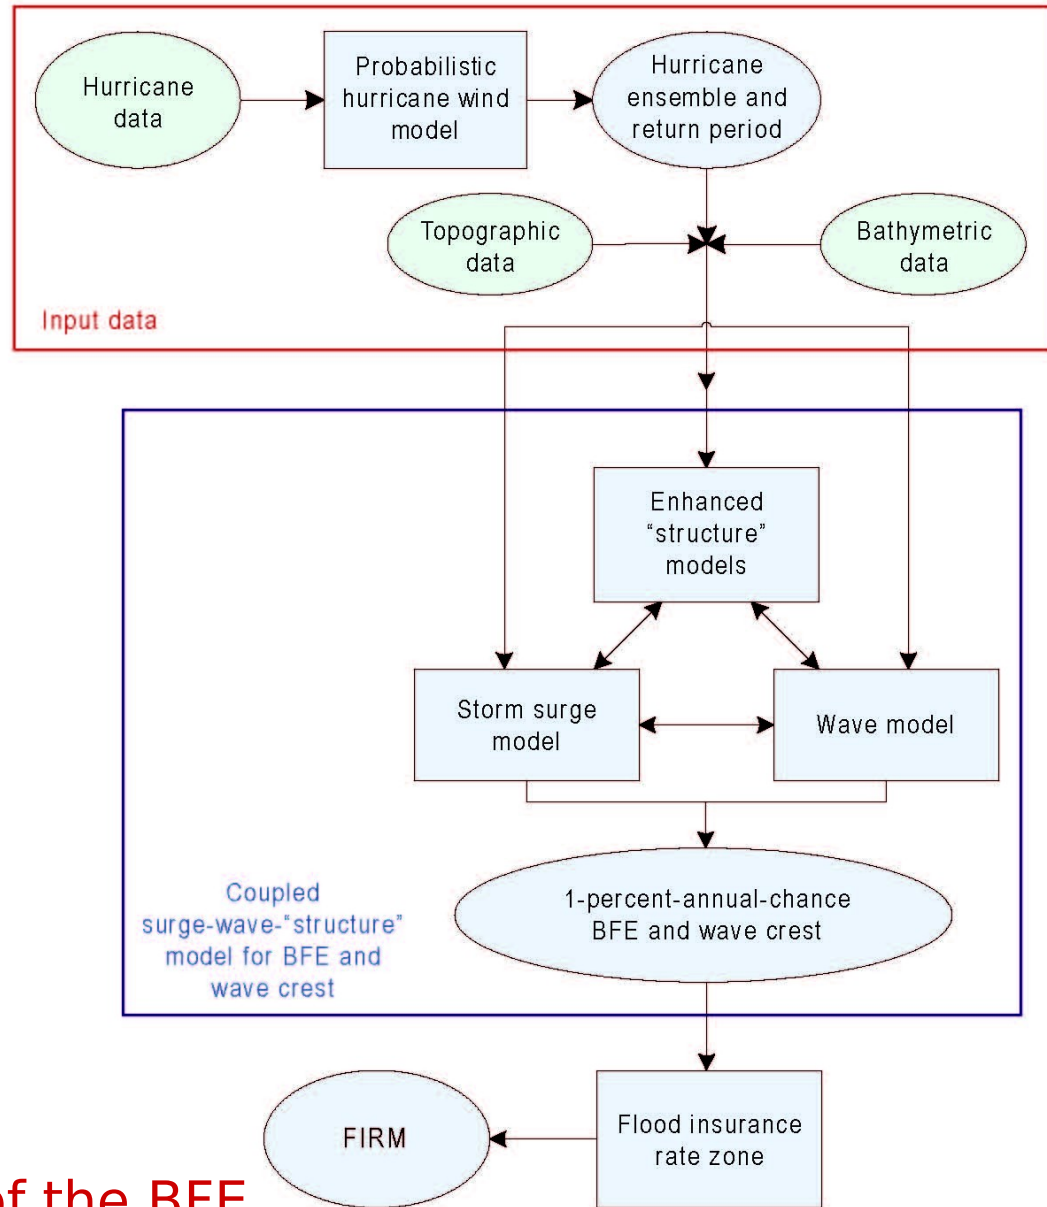

Wave and erosion phenomena are treated separately from the storm surge modeling

Proposed Coastal flood mapping methodology

- Advances from academic research
- 1-D to 2-D and 3-D
 - coupling process models
 - additional processes e.g.

To improve accuracy of the BFE

Coastal Bathymetric Data

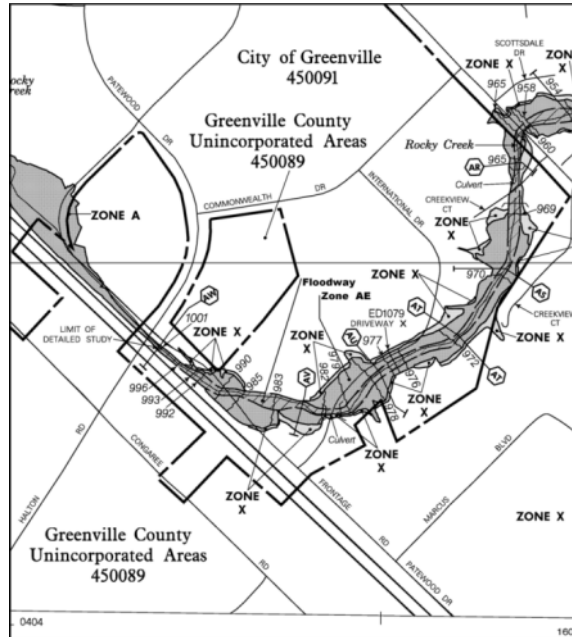

- Waves start to sense the sea floor when the depth < 40 ft
- Most critical zone for accurate bathymetric data is in the near-shore coastal environment and in coastal bays and inlets
- Barrier islands are important but difficult to deal with in storm surge simulation
- Model uncertainty \gg bathymetric data uncertainty

Presentation Outline

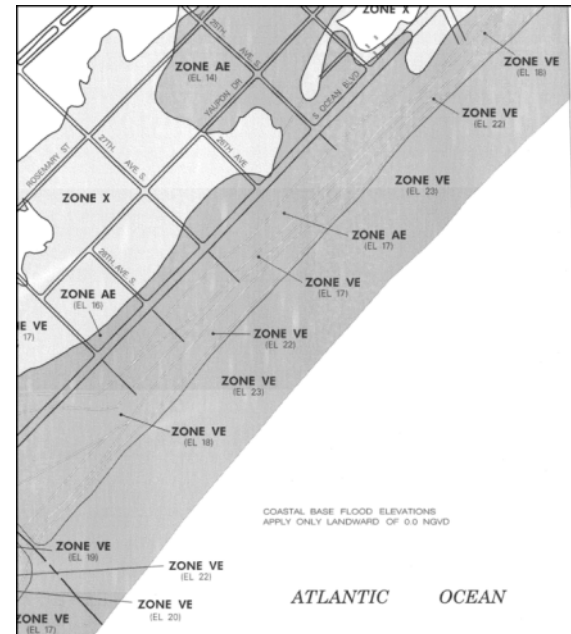

- Overview of Committee Charge
- Review of Elevation for Floodplain mapping study
- Mapping the Zone Report Chapters
 - 1-3 Overview of flood mapping and terrain data
 - 4-5 Inland and Coastal flood mapping
- *Overarching Findings*

Flood Maps

Riverine

Coastal

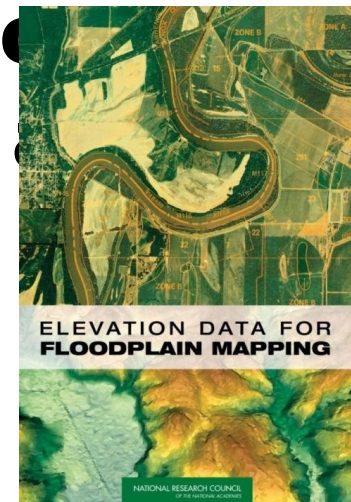

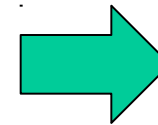

Two **very different** flood modeling and mapping problems

Overarching Finding

1. Topographic data is the most important factor in determining water surface elevations, base flood elevation, and the extent of flooding, and thus the accuracy of flood maps in riverine

This finding reinforced the conclusion of the earlier study

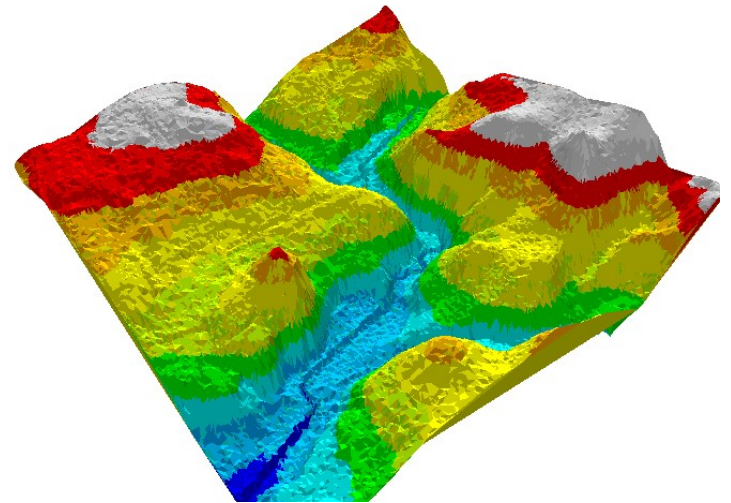

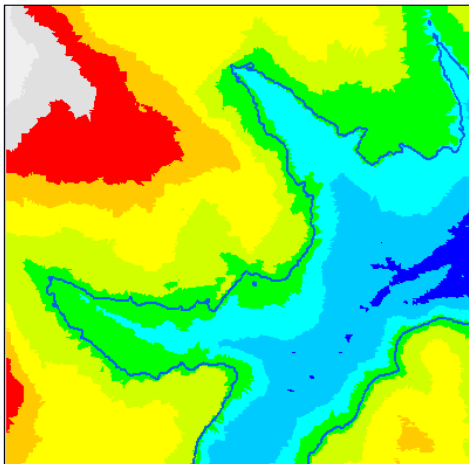

Overarching Finding

2. **Coastal** flood maps can be improved significantly through use of **coupled two-dimensional storm surge and wave models** and improved **process models** for dealing with erosion and other processes

Overarching Finding

3. Flood maps with base flood elevations yield greater net benefits than flood maps without such elevations

Bottom Line

- Riverine Flooding
 - Elevation, elevation, elevation
- Coastal Flooding
 - Inundation process is complex
- Economic Analysis
 - Base flood elevations are worth the cost
- Risk Mapping
 - Better maps can provide good risk information
